A PRINCIPLE IN RASPBERRY LEAVES WHICH RELAXES UTERINE MUSCLE

BY

J. H. BURN,
M.D. CAMB.
PROFESSOR OF PHARMACOLOGY, OXFORD

E. R. WITHELL,
B.SC., B.PHARM. LOND., PH.C.
HEAD OF THE PHARMACY DEPARTMENT, CENTRAL TECHNICAL COLLEGE, BIRMINGHAM

RASPBERRY-LEAF tea has been a herbalist's remedy for many years. It is said to be the best known and oldest of all the herb infusions and to be included "as a proved aid in maternity in the most ancient of herbal books." Our interest in it was stimulated by an inquiry made to one of us (E. R. W.) by Sir Beckwith Whitehouse whether anything was known of the action of raspberry leaves in the body.

The statement made by one firm of herb specialists is as follows: "Raspberry leaves are the dried leaves of *Rubus idæus* (Rosaceæ) which grow in Europe, Canada and northern United States. The leaves impart their properties to water, giving to the infusion an odour and flavour somewhat similar to that of some kinds of black tea. Raspberry leaves have astringent properties and also act as a stimulant. It is found that if the infusion be taken freely before and during confinement, parturition is easy and speedy." It is also said to be useful in painful and profuse menstruation. We have accordingly tested extracts of raspberry leaves for their action on the uterus both in situ and when isolated. In the course of this work we have found that a principle is present which causes relaxation of the muscle of the uterus when this is tonically contracted, and which diminishes the force and frequency of rhythmic contractions. We have also made a general survey of the action of raspberry-leaf extracts on other tissues.

PREPARATION OF EXTRACTS

Active extracts have been made in the following ways:

(*a*) By making an infusion of the dried leaves with boiling water, using 100 ml. of water for 10 g. leaf. This was allowed to stand for half an hour and then squeezed through muslin. The infusion was concentrated by evaporation at 40° C. under reduced pressure until the activity of 2 g. leaf was present in 1 ml.

(*b*) By evaporating to dryness an infusion prepared as in (*a*). Approximately 1 g. residue was given by 10 g. leaf. Of the residue 1 g. was taken up in 5 ml. distilled water, and 5 ml. absolute alcohol was added. This produced a precipitate of inactive material which was removed by filtration. The filtrate was taken to dryness. Of the residue 1 g. was equivalent to approximately 20 g. leaf.

(*c*) By preparing an infusion as in (*a*) (before concentration), and adding basic lead acetate in amount just insufficient to throw down all precipitable matter. The filtrate was evaporated to dryness.

(*d*) By treating an infusion prepared as in (*a*) (before concentration) with Norit charcoal, filtering and evaporating to dryness.

Other steps to purify the active material have been taken, but these are still in progress and will be described elsewhere.

PHARMACOLOGICAL ACTION

Action on uterus of cat in situ.—The action of raspberry-leaf extracts on the uterus has been examined by intravenous injection into spinal cats, prepared by destroying the brain under ether, and into cats anæsthetised with chloralose. The stomach, the small and large intestines, the pancreas and the spleen were removed, and the abdominal cavity was filled with Ringer's solution at 37° C. The ovarian end of one horn of the uterus was freed from its attachments, though its blood-supply was preserved, and the end of the horn was connected by a thread passing over light pulleys to a lever writing on a smoked drum.

The injection of an amount of extract equivalent to 2 g. leaf into the external jugular vein produced a relaxation of the uterus as shown in fig. 1, accompanied by a slight rise of blood-pressure. The effect on the uterus was variable. Instead of the simple relaxation seen in fig. 1, occasionally the relaxation was followed by contraction. Sometimes there were three phases: (*a*) relaxation, (*b*) contraction and (*c*) further relaxation. Often the effect seen in fig. 1 was not obtained with the first injection, but as successive injections were made the relaxation became increasingly pronounced. This is shown in fig. 2, in which the 2nd injection of extract produced no more than a longer pause between two contractions, as shown in fig. 2A, while the 4th injection stopped the contractions for 10 minutes. The 5th injection led to complete arrest of all uterine movements, the muscle being fully relaxed.

While extracts made by the process (*b*) had no great effect on the blood-pressure, extracts prepared as in (*c*) often caused an initial fall of blood-pressure followed, especially in spinal cats, by a rise which was sometimes large; in one experiment the blood-pressure rose from 78 to 196 mm. Hg. The concurrence of a rise of blood-pressure and a relaxation of the uterus at first suggested that both effects might be due to the liberation of adrenaline from the suprarenal glands by the action of some substance in the extract resembling nicotine. Several experiments were necessary to establish that the suprarenal glands played no part in the action on the uterus, and that complete relaxation with cessation of rhythmic contractions was produced in the absence of these glands.

We tested the action of extracts of raspberry leaves not only on the uterus of the virgin cat but also on the non-pregnant multiparous cat and on one cat in late pregnancy. The record obtained before the injection showed large contractions at intervals of 2–3 min. superimposed on a regular rhythm of smaller contractions. When the raspberry-leaf extract was injected the large contractions were abolished during 10 min. while the series of smaller contractions persisted.

Action on uterus of rabbit in situ.—When similar preparations of the uterus in situ were made in the rabbit, using urethane as an anæsthetic, relaxation was not observed to follow the injection of raspberry-leaf extract. Instead a contraction of short duration was seen. Since the rabbit's uterus also contracts when adrenaline is injected, we at first thought that the observation was further evidence that the effects of raspberry-leaf extract were due to the liberation of adrenaline. We do not think that this is so, but that in the rabbit the phase of contraction which is often seen in the cat is the main effect. The uteri of the parous rabbits we used were thicker than those of the cat, and it may be that a much larger amount of raspberry-leaf extract is needed to produce relaxation in the rabbit. That the effect is not due to adrenaline is borne out by the similar stimulant action on the isolated uterus.

Action on isolated uterus.—We have tested the action of extracts on the isolated uterus of the dog, the cat, the rabbit and the guineapig. The two actions of the extracts are well seen in the isolated preparation. The uterus of the dog or cat when first suspended usually remains for some time tonically contracted. If extract of raspberry leaf be added to the bath, the uterus relaxes as shown in fig. 3A. If however the uterus has been suspended for some time the muscle gradually relaxes, and when extract is added to the bath a contraction occurs. If the tone is restored in a cat uterus by the addition of pituitary (posterior lobe) extract to the bath, raspberry-leaf extract then once more causes relaxation.

The uterus of a rabbit has little tone when suspended in a bath and is stimulated by the addition of raspberry-leaf extract, but if a tone is produced by the addition of adrenaline, raspberry-leaf extract relaxes the tone. The only effect we have observed to be produced on the isolated guineapig uterus is that of contraction.

Action on intestine.—We have examined the action on the intestine both in situ and in isolated strips. We inserted a small balloon into the duodenum of a cat through an incision lower down. The balloon filled with water was connected by a catheter to a piston recorder which recorded the changes of pressure in the balloon. The suprarenal glands were removed in these experiments. Injection of raspberry-leaf extract caused a fall of pressure in the balloon due to arrest of the intestinal contractions and relaxation of the musculature which persisted for about 3 min

The extracts were found to relax strips of rabbit intestine suspended in a bath Fig 3B shows the effect of two different extracts The results with these two extracts suggest that the substance which causes stimulation of plain muscle is different from that which causes relaxation Thus the addition of the first extract shown in fig 3B caused an initial contraction before the following relaxation The addition of the second extract prepared by extracting the leaf with dilute acetic acid caused relaxation only

Action on spleen —When the volume of the spleen was recorded in a spinal cat, injection of raspberry-leaf extract did not cause contraction of the spleen volume, though injection of 0 02 mg histamine, which is known to cause discharge of adrenaline from the suprarenal glands, did so

Action on heart and blood-vessels —Extracts prepared by method (*a*) have a slight depressant action on the heart of the cat when isolated and perfused by Langendorff's method The extract was injected into the cannula leading to the heart Similarly if the vessels of a dog's hind-leg are perfused with defibrinated blood, using a Dale-Schuster pump, the injection of an extract into the arterial cannula causes a transitory dilatation of the vessels followed by constriction slightly greater than the pre-existing constriction

Toxicity —The toxicity has been tested by administering the extracts to mice both by mouth and intravenously Using an extract prepared by method (*b*), dissolved in distilled water so that 1 ml contained the activity of approximately 4 g leaf, it was found that doses of 0 5 ml had no harmful effect on mice when given by mouth When injected intravenously the mean lethal dose of such a solution was 0 1 ml per 20 g mouse, corresponding to about 0 4 g leaf Mice injected with a lethal dose had convulsions and died Convulsions were observed to follow the intravenous injection of extracts prepared by method (*a*) into cats

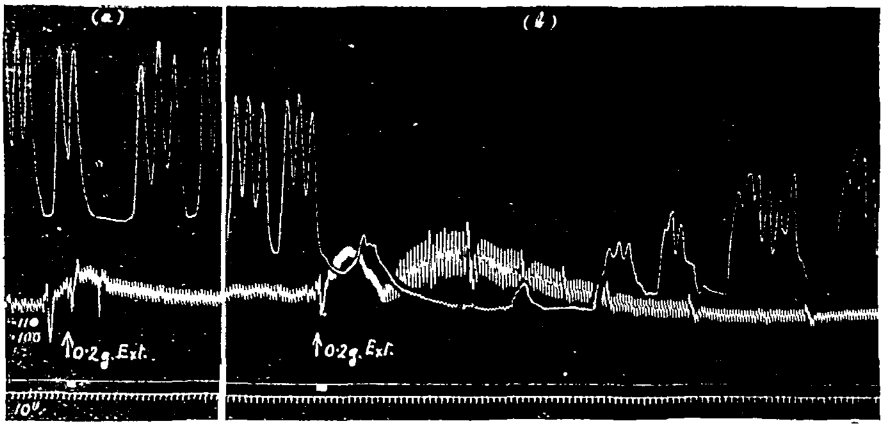

FIG 2—Records as in fig 1 (A) shows the slight effect of the 2nd injection of raspberry leaf extract, (B) shows the prolonged effect of the 4th injection

DISCUSSION

It is very surprising that raspberry leaves should offer themselves as a new field for pharmacological investigation, and that principles having physiological activity should not have been discovered earlier During the course of the work, results similar to that in fig 1 suggested that the activity was due to an amine like tyramine, this was excluded by the stimulant action on the isolated guineapig uterus It was next thought that the activity was due to nicotine or to a substance having a similar action on the uterus, like hydrastinine The nicotine suggestion was attractive because raspberry leaves were smoked during 1914–18 in Germany It was supported by the twitching of the ears and body muscles observed to follow the intravenous injection of crude extracts into spinal cats Accordingly we
densed the smoke coming from a pipe of raspberry le
and looked for nicotine in the deposit None
present Laidlaw[1] found that hydrastinine inhil
the uterus of the cat in situ, but stimulated it to con
when the uterus was suspended in a bath , hydrast
also stimulated the uterus of the rabbit in situ,
stimulated the isolated guineapig uterus These obs
tions resembled many observations with raspberry
extracts Nevertheless these observations did not c
the actio
chief import
exerted by
berry extra
namely, a r
ation of ut
muscle in

isolated ut
of the dog,
and rabbit w
this is in t
We do not k
whether t
principle is
the one w
stimulates the uterus of the rabbit , there is some ind
tion that the two are not the same Other substa
are known which have both a stimulant and a rela
action on the isolated uterus Thus Gunn[2] has sh
that harmine has both these effects on the rabbit ute

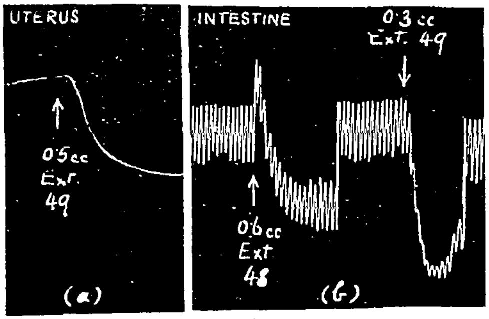

FIG 3 —(A) Record showing inhibition of tone of isolated uterus of dog (B) Record showing inhibition of isolated intestine of rabbit

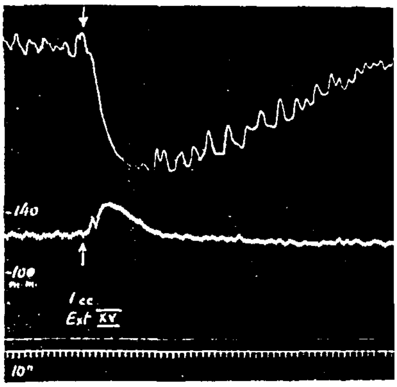

FIG 1—Record of cat's blood pressure (
chloralose) and of uterine movements, sh
relaxation of uterus produced by inj
of extract equivalent to 2 g dried leaf

The fact that raspberry-leaf infusion has a traditi
use (though not a widely known one) to make ute
activity "easier," suggests that the observat
described may have a clinical application It is diffi
to understand how uterine relaxation should as
parturition , rather it would be thought to delay it
diminishing the force available to bring about the b
of the child Conceivably it may assist in dilatatio
the os through being exerted chiefly on the lower ute
segment But a drug which relaxes uterine mu
should be valuable in relieving painful menstrua
when this is due to spasmodic contraction of the ute
The dosage recommended by herbalists is 10–20 oz
a 5% infusion of the dried leaves in hot water T
corresponds to 15–30 g of leaf, and, judging from
observations on mice, should be entirely non-toxic w
taken by mouth

SUMMARY

Dried raspberry leaves contain a principle read
extracted with water which relaxes the smooth mus
of the uterus and intestine when this is in tone T

---

[1] Laidlaw, P P *Biochem J* 1911, 5, 243

[2] Gunn, J A *Arch int Pharmacodyn* 1930, 38 507

action is exerted in the body of the cat and also when the muscle is suspended in a bath The relaxation produced in the body increases with successive doses

The same principle or another causes contraction of the uterus of the rabbit in situ, and also of the isolated uterus of the cat, the rabbit and the guineapig when these are not in tone

The principle causing relaxation is probably the basis of the traditional use of raspberry tea for making activity in the uterus less painful

IN view of the encouraging reports published on the Continent and in America of the therapeutic effects of prefrontal leucotomy, it was considered justifiable, and indeed advisable, to employ this method of treatment here, and 8 of our patients have now been operated on by Mr Wilfred Willway

Review of the Literature (Dr. Hutton)

Owing to the war a survey of European and American literature must be incomplete, for many of the original articles are now unobtainable

Prefrontal leucotomy has been widely adopted, since its introduction by Moniz in 1936, among other exponents being Rizzatti (Racconigi), Bagdasar and Constantinesco (Bucarest), Pimenta (Saô Paolo, Brazil), Sai (Trieste), Lyerly (Florida), Watts and Freeman (Los Angeles), Ventura (Pisa), Ody (Varese); Ferdière (France), and Mixter, Tillotson and Wies (U S.A) The total number of recorded cases cannot be assessed, but Rizzatti and Borgarello (1940) estimate them as at least 500 I have compiled a list of 330 of these

			Year
Rizzatti and Borgarello	185		1940
Moniz	46	Quoted by Rizzatti and Borgarello	1938
Sai	3		
Fiamberti	10		
Bagdasar and Constantinesco	10		
Lyerly	21		1938
Freeman	54		1939
Mixter	2		1940

Out of this total only 5 deaths are recorded as being due to the operation, 2 by Rizzatti and Borgarello (1938) and 3 by Freeman (1939) Freeman gives no details of his 3 deaths, but Rizzatti and Borgarello state that in both their cases death was due to hæmorrhage into an unsuspected frontal glioma

Most recent investigators agree that the frontal lobes, which reach their highest development in man, are in some way concerned with mental processes, and in particular with the higher intellectual processes , and that this fact is correlated with the magnitude and complexity of the prefrontal association tracts Moniz (1936), in discussing the theory which led him to propose frontal leucotomy, considers that whereas in normal people the functional connexions between the cortical cells are variable, giving rise to innumerable different groupings, in certain mental disorders some functional groupings become more or less fixed and give rise to obsessions and delusions Considerable mental improvement might thus be expected from cutting the association fibres concerned in these persistent pathways He was cautious in adopting this experimental form of treatment, and his earliest cases were limited to chronic patients with a poor prognosis The results in the first 20 cases, however, were encouraging , some patients were undoubtedly improved, there were no deaths, and in no instance was the mental condition made worse by the operation

TECHNIQUE AND REPORTED EFFECTS

Technique—The procedure first developed by Moniz consisted in the injection of alcohol into the subcortical white matter , in later cases a leucotome was used with a steel loop, which crushed the white matter in the subcortical area , finally he adopted a leucotome with a steel band which cuts rather than compresses He claims that with his latest technique the symptoms that followed the earlier methods are rarely observed

The original trephine openings were made 3 cm in front of a vertical line passing through the base of the tragus, and 3 cm to either side of the midline, but later the openings were made a little farther back—1 5 cm in front of the vertical line passing through the tragus The leucotome is introduced to a depth of 4 5 cm in an anterolateral direction, the loop is opened and the instrument turned so as to cut a core about 1 cm in diameter in the white matter The blade is retracted into the instrument which is withdrawn 1 cm and a second core cut at 3 5 cm and finally a third at 2 5 cm from the surface of the brain No tissue is removed The leucotome is then withdrawn entirely and reintroduced in an antero medial direction to a depth of 4 cm , where the first cut is made and withdrawn 1 cm to cut a second core at 3 cm , a final section is made at 2 cm from the surface of the brain

Rizzatti and Borgarello (1938) do not seem to have introduced any noteworthy modifications of Moniz's methods , in 55 of their cases the operation was performed with the leucotome devised by Moniz, in 28 with a thermocoagulator, in 5 by the introduction of alcohol In a large number of cases where leucotomy was performed by the leucotome or the thermocoagulator it was followed by prefrontal alcohol injections, a total of 393 injections being given Rizzatti and Borgarello note that Fiamberti in 1937 used the method of transorbital puncture devised by Dogliotti for ventriculography Lyerly (1939) and Freeman (1939) have both modified the technique

Choice of patient—Moniz deliberately decided not to limit his operative measures to a single psychosis or even to a single group of psychoses , indeed, since his aim was to attack association pathways, not only functional but even organic psychoses were to be included in order that any modification in the symptomatology might be observed Among his cases were patients suffering from agitated melancholia, schizophrenia, mania and acute anxiety , only patients with dementia were excluded Rizzatti and Borgarello treated mainly schizophrenics, but their 185 cases included a few paranoiacs, melancholics and patients with disorders of conduct Lyerly (1938) restricted his choice to patients with depression—mainly involutional melancholics—together with a few psychoneurotics, manic depressives and 1 schizophrenic Freeman chose involutional or agitated depressions, psychasthenics or schizophrenics, in whom worry was a predominant factor exhibited in the form of nervous tension, apprehension, anxiety depression, insomnia, obsessive thinking, preoccupation and introversion

Immediate postoperative effects—Moniz (1936) describes a number of mild symptoms of a transitory nature which were present during the first 2 or 3 days after the operation, and in a few instances persisted for 2–3 weeks In every case there was a slight rise of temperature which returned to normal about the fourth or fifth day, headaches were usually present but rarely severe, there was occasional vomiting, and somnolence was usual on the first day after the operation and lasted 1–2 days The neurological signs noted included trismus and fibrillary contractions affecting the masseter and platysma muscles, sphincter disturbances, mostly slight but sometimes severe, and accompanied by diarrhœa, and ocular disturbances in the form of Argyll Robertson pupils, myosis, unequal pupils, ptosis and in one case nystagmus Mental disturbances also occurred—apathy and loss of initiative in about half the cases, akinesia in about a third, resistance to the execution of movements, mutism, negativism, loss of facial expression, and disorientation in space and time in several Catatonic attitudes, kleptomania and a sensation of hunger were noted in a few cases and puerility was observed in one Moniz claims, however, that after the adoption of his later technique with the cutting leucotome the above symptoms were rarely observed, except for ocular signs (sluggish and unequal pupils) which lasted only a few days. Rizzatti and Borgarello (1938) describe transitory aphasia and hemiplegia in 7% of their cases, vomiting and convulsions in 40%, and fever lasting for at least 48 hours in 49%. Lyerly (1938) claims to have had no serious complications resulting from the operation. A small number of patients had urinary incontinence for a few days, but no other neurological signs were found. Mentally there was some slight impairment of memory and disorientation with mental confusion lasting a few days to a few weeks, but it always cleared up entirely. Freeman also mentions slight headache, loss of facial expression, absence of spontaneous activity and disorientation in time and space.

Published results.—The best results appear to have been obtained in patients suffering from depression or acute anxiety; Moniz writes that this operation has a remarkable action in cases with anxiety (see table). Freeman (1939) analysed the symptoms in his 54 patients under 35 heads which included, for example, such things as anxiety, worry, nervous tension, obsessive thinking and apprehension; he noted which of these was relieved—completely, partially or temporarily—by operation and tabulated his results. It is noteworthy that anxiety, which was present in 49 of his cases, was permanently relieved in 36, partially relieved in 4, and temporarily relieved in the remaining 9. Rizzatti and Borgarello (1940) chose principally schizophrenic patients (128 out of a total of 185). Of the 128 only 10 were acute cases; the remainder were chronics who had derived no benefit from other methods of treatment, such as malaria or vaccine therapy. They consider their results encouraging and claim that the number of recoveries increased with the period of observation. Critical evaluation of their figures is difficult, however, owing to the obscure way in which they are presented.

RESULTS OF LEUCOTOMY, COMPILED FROM CASES REPORTED IN THE LITERATURE

—	Cases	Diagnosis		Results			
				Recovered	Improved	Stationary	Dead
Moniz (1936)	20	Agitated melancholia	7	5	2		
		Schizophrenia	8		3	5

* Quoted by Rizzatti and Borgarello 1938.
† 1 case too recently operated for results.

Spontaneous recovery must always be considered when the efficiency of any therapeutic method for mental diseases is under discussion. A careful study of the time relationships between the onset of symptoms, the institution of treatment, and the date of recovery will con
towards a correct assessment of its importance
first series, Moniz included some recent cases as
some of long standing. Of 10 patients with a
melancholia or acute anxiety 5 had been in hosp
periods ranging from one to eight years, while i
symptoms had only been present for a few months
recoveries recorded all seem to have taken place
the first two months after the operation. It is i
tive to note that recovery occurred in a patien
involutional melancholia two months after the op
though she had previously been in hospital fo
years. In the series reported by Rizzatti and Bor
(1938) the average duration of symptoms before
tion was nine years for the hebephrenic group, fou
for the catatonic group and six years for the par
The recoveries did not occur until a considerabl
after the operation. In Lyerly's series there
14 cases of involutional melancholia, in who
longest history was more than ten years an
shortest four months; in 5 patients the sympto
been present for two to ten years, and in the rem
for less than two years. All recovered cases we
charged within two and a half months of operatio

Prefrontal leucotomy seems to be rarely follo
undesirable sequelæ. Moniz reports none in his f
cases. Rizzatti and Borgarello say that none o
patients show any permanent frontal disturbance
operation. Lyerly also claims that there were no s
postoperative complications, and most of his p
said they could think better and do more work
before. Freeman reports rather more operativ
turbance, mainly transitory. Emotional flatt
procrastination, diminished spontaneity and la
persisted in about 25 of his 54 cases; poor judg
talkativeness, facetiousness and euphoria in 7–10;
lessness, aggressiveness, perseveration and indece
2–4; a permanent gain in weight occurred in 22, inc
appetite in 15, plateau speech and masked facies i
convulsions in 3, vesical and rectal incontinence in
monoparesis in 1.

Psychological tests have been used by Lyerl
Worchel (1941) and by Freeman in an attempt to
any psychological change produced by the operatio
Lyerly and Worchel's series use was made of the
intelligence tests, and the Terman vocabulary, but th
change observed which seemed at all significant was f
to do the "free association" test of the Stanford-
intelligence examination. Of 10 patients tested aft
operation all but 1 failed the test, although 4 out of 5 t
prior to operation had passed it successfully. Fre
(1939) quotes the report of Thelma Hunt who tested
his cases before, and two weeks after, the operation
found less distractability and more satisfactory co
tion after leucotomy, although initiative in startin
tests was somewhat less. Patients were less conc
over incorrect performance, and were slower in ca
out the tests. There was no sign of decrease in
intelligence and accuracy on the average was imp
In the interpretation of pictures, and in other
lending themselves to such a response there wa
tendency to interpret in relation to the self. I
Rorschach test patients were inclined towards e
version and tended to respond to the design as a w
whereas in the word-association test they showed
peculiar responses and hesitated less, and the total
was lowered. The Bernreuter extroversion-introv
test indicated a shift toward extroversion, with low
in the neurotic tendency.

The problem of the function of the frontal lobe
awaits solution. There are grounds for supposing
they are concerned with the higher intellectual proc
but the results of prefrontal leucotomy indicate th
certain pathological conditions they impair rather
enhance the efficiency of the individual and pla
important part in the symptomatology and perhaps
in the ætiology of mental disorders. Thus the wo
Moniz not only has therapeutic value but contribut
the study of normal and abnormal psychology.

Results in Present Series

Moniz himself exercised the greatest caution in
selection of his early cases and his example has
followed in our series; the cases chosen were all of

standing with a bad or hopeless prognosis, and most of them had been intensively but unsuccessfully treated by other methods, any improvement obtained therefore may be regarded as an achievement Much time must elapse before any decisive conclusions can be reached, but this preliminary report on the immediate results of the operation is published now because we feel that the method requires careful investigation whatever the final decision on its value may be

TWO SCHIZOPHRENICS IMPROVED

CASE 1 —A woman, aged 26, who had undergone insulin and other endocrine and electrical convulsive treatments with no conclusive or permanent result She had schizophrenia of 4 years' duration Since admission to Brislington House she had been resistive, negativistic and destructive, and was rapidly deteriorating She was constantly in a state of morbid apprehension reiterating "What am I to do?" Over a period of 11 months she had 77 electrically induced convulsions She reacted well at first, becoming mentally stable for periods of 3–5 weeks Later stability lasted only a few days During one remission she went home on leave, but after a few days became unmanageable She seemed suitable for surgical treatment because she was a worrying type and had reacted well to the electrical treatment

Prefrontal leucotomy was performed under local anæsthesia on Dec 11, 1940 She was quiet and coöperative during the operation and willing to answer questions Immediately after operation she appeared comfortable and sat up in bed and drank a cup of tea Her predominant facial expression of mental strain and tension faded away and she rapidly fell asleep She slept excessively during the first 48 hours but could be roused when necessary When wakened she gave brief but relevant answers to questions and coöperated with the nurses attending to her, but she fell asleep almost instantaneously if she was left undisturbed. There was an attack of vomiting and diarrhœa on Dec 18 A slight rise in temperature (99° F) subsided on Dec 19, the pulse and respiration remained steady Mentally she was dull, confused and moody, at times restless and noisy On Jan 11 she began to take an active interest in her surroundings, helped the nurses in the hospital, and showed attention to her work and books During this postoperative stage she was subject to bed-wetting until Jan 28 She went home on Feb 15 and reports on her progress have been satisfactory, she still has occasional enuresis—a failing of which she is aware but which she is unable to overcome completely at present She is rather childish and dependent on her mother's supervision, but rational and can converse simply but sensibly She has a moderate degree of insight compatible with her childish outlook. Her previous history, however, suggests that she never had more than a modest degree of intelligence She is now partly occupied and able to earn some of her living in a small way

CASE 2 —A woman aged 35 Catatonic stupor with occasional outbursts of impulsiveness and maniacal excitement She showed much apprehension and nervous tension, and frequently repeated without apparent cause, "Is it all right for me to do this?" She was admitted to Brislington House in 1937, and was treated by electrical convulsive methods at the end of 1939, having 14 treatments in all The result was satisfactory and after 2 years of stupor alternating with maniacal outbursts she returned home, the remission lasted for 11 months She was readmitted on Nov 16, 1940, electrical convulsive treatment was again given on 9 occasions She improved mentally and returned home, but within a month (during which time she experienced a severe air raid) she returned for further treatment, and remission obtained this time was only of short duration

On Feb 19, 1941, leucotomy was performed under local anæsthesia Throughout the operation she was composed and coöperative and answered questions There was no sign of confusion or distress immediately after the operation, and no indication of shock. Afterwards the temperature was raised (never above 100° F) until Feb 23, pulse and respiration remained steady There were mild attacks of nausea and a little vomiting for 3 days At first she was rather confused and restless and tried to dislodge the dressings, but as soon as she was up and dressed she began to take an interest in herself and her surroundings She left hospital on April 2 Since the operation there has been periodical bed-wetting which distresses her Except for this, and for some delay in dressing herself in the morning, she is very well mentally and quite stable Reports of her progress are satisfactory

HYPOCHONDRIAC IMPROVED (FATAL HEART ATTACK)

CASE 3 —A man, aged 53, of considerable intellectual attainment, admitted to Brislington House in September, 1940, with a 3 years' history of severe hypochondriasis He complained incessantly of severe pain in the lower abdomen and penis Previously in 1938 bilateral chordotomy at the level of the 6th dorsal had been performed, but the pain had returned within 3 days Considerable physical and mental deterioration had taken place since then He was a tall and well built man but his weight had fallen to 8 st 10½ lb He was restless—writhing on his bed and very noisy—and incontinent with bed sores There had been a history of myocardial degeneration with inversion of the T wave in the electrocardiogram Convulsion therapy, 20 treatments, was given with satisfactory results, the pain was much alleviated and the heart condition was not aggravated. He put on over 2 st in weight, felt better and became mentally clear and composed During December the remission showed signs of fading out, more electrical treatment was given without satisfactory improvement The pain in the abdomen and the genitals again became intense and at this time auricular fibrillation was noted, but he was able to tolerate convulsive treatment without distress The pain persisted, although mentally the patient remained clear Since he had been able to tolerate convulsive treatment without undue strain on the heart, it was decided to proceed with the surgical treatment

Leucotomy was performed under local anæsthesia During the operation the patient was constantly complaining of his pains until the actual division of the tracts when he suddenly became composed After removal from the theatre he said the pain in his abdomen and penis had gone—for the first time in 3 years—and he felt comfortable It appeared that the whole object of the operation had been achieved Unfortunately during the latter part of the day there was a severe heart attack which initiated a state of hypostatic pneumonia, from which he died 2 days later At autopsy he was found to have much myocardial fibrositis, and atheromatous pipestem coronary arteries Death was undoubtedly due to the cardiac condition and not to the operation

TWO DEPRESSIVES IMPROVED

CASE 4 —A man, aged 42, who described himself as a nervous wreck since the last war He had frequently been off work because of nervous upsets He had always been reserved, solitary, self-absorbed and intolerant of noise, with no friends or hobbies, he had suffered from nightmares for many years An acute attack of anxiety was precipitated by an air raid He was working as a builder's labourer at the time, and after having to clear up a shelter which had been hit he was unable to eat or sleep for 3 days, and just wandered round the streets hardly knowing what he was doing He gave up his job and for 3 weeks continued to wander aimlessly about the streets He then got a job but could not concentrate and became a nuisance at home He could not stand any noise and was always listening for sirens On admission in February, 1941, he was mildly anxious, well orientated with good insight, and depressed rather than agitated. If he tried to do anything his mind wandered off and he began to think about his home, his work and air-raids He discussed his family in a dull unemotional way, his whole mental outlook had narrowed to preoccupation with himself and his nerves

On Feb 19 leucotomy was performed under local anæsthesia For 4–5 days there were alternating phases of restlessness and somnolence He would get out of bed and attempt to dress and tidy his room, he removed his dressing frequently, and once sang loudly during the night, waking the other patients During the first 2 days he wrote several nonsensical letters, and his conversation was irrational, but he was conversing sensibly about the third day Disorders of behaviour persisted for about 14 days, he would play with food instead of eating it, would unashamedly urinate on the floor in the ward, and would drape his wet linen round the radiators in the ward to dry He exhibited a rather fatuous euphoria Gradually his conduct improved, he became less indolent, and began to share in the routine work of the ward The most striking change was his indifference to air-raids Several severe raids occurred while the patient was in hospital but he paid little attention and was in no way distressed He was usually asleep before the all-clear went He also lost the nightmares with which he used to be troubled before his admission He remained rather apathetic A mental test suggested that he did not associate quite as freely as formerly There were no neurological symptoms He was discharged on April 16 and returned to work the following week. He first tried his old job of commissionaire, but his work was not very satisfactory and he was extremely unpunctual He seemed to appreciate that his unpunctuality would probably lose him the job but the intellectual appreciation seemed to have no emotional accompaniment It was suggested that he should be given a simpler job with less responsibility and more supervision, he was therefore employed as a porter and cleaner, and since then has been efficient and punctual The former anxiety connected with air raids has apparently completely disappeared, and his indifference to them noted while in hospital has persisted since his return home He reads a good deal and enjoys listening to the wireless He is no longer self absorbed and preoccupied but is interested in current affairs, which he can discuss quite intelligently Unfortunately there is friction in the home, probably attributable to the patient's preoperative personality Before operation his wife complained that he never took any interest in herself or the children Owing to her vague hostility and lack of sympathy the postoperative changes in the patient's character are misunderstood and misinterpreted, this may have a deleterious effect on his reintegration He describes the change from his former miserable introspective brooding to his present carefree outlook as the most important thing that has ever happened to him

CASE 5 —A Jewish man, aged 58, with agitated melancholia, admitted to Barnwood House in 1935 from Brislington House, where he had been for 5 months Before admission he had tried to cut his throat He had previously been in Barnwood House in 1928, after two attempts at suicide, but recovered rapidly in 2 months There was no family history of insanity or abnormality Between 1929 and 1935 he had remained well and at work On his medical certificate in 1935 it is stated that he asked his nurse to " lacerate his brains " While in Brislington House in 1935 he tried to choke himself with his dentures, and after his admission to Barnwood House he remained depressed and agitated, saying that he was afraid of being dropped overboard from an aeroplane He was tube-fed for some time after admission, and had traces of sugar in his urine until 1937 Apart from time spent playing billiards and snooker, he was restless and agitated, reiterating his stereotyped phrases about aeroplanes and fearing injections and giddy heights He had shown no suicidal tendencies for 3 years

On April 2, 1941, a bilateral frontal leucotomy was performed under pentothal anæsthesia with Nembutal premedication The operation was uneventful, after it he remained drowsy for some days and developed bronchopneumonia with a temperature up to 103 8° F Treatment with sulphapyridine reduced his temperature somewhat, but irregular fever persisted for 21 days He was enuretic all the time he was confined to bed, and occasionally after being allowed up, this symptom did not disappear until the 28th day He showed no abnormal neurological signs and symptoms apart from general drowsiness Now, a month after operation he is gaining strength, and walking round the garden, his relatives consider that he has improved He smiles spontaneously, takes more interest in his surroundings, and has gained 16 lb in a month He still talks about the aeroplanes and seems to be somewhat vague about dates, not being able to remember when he was admitted but he is much less agitated than he was formerly It is too early to hope for much improvement yet

THREE SCHIZOPHRENICS NOT IMPROVED

CASE 6 —A man, aged 31, with schizophrenia was admitted to Barnwood House from Wyke House, Isleworth in 1931, the duration of his illness was then one year There was no physical abnormality apart from undescended testicles He had been at Oxford but is stated " not to have got on well " He went into an office but subsequently broke down and was sent to Wyke House He has been a catatonic schizophrenic since admission, with periodic attacks of excitement during which he was noisy and destructive and had to be put in the padded room These catatonic excitements lasted for anything up to 3 or 4 months In the intervals he was quite pleasant and played tennis well While in hospital he had been the subject of a concentrated therapeutic attack lasting many years, beginning with testicular hormone and colloidal calcium His blood iodine was estimated in 1933 at the Middlesex Hospital, hyperfunction of the thyroid was reported and a course of Tyronorman and a salt free diet for 6 months was advised In 1934 the character of his attacks changed, treatment with acetylcholine and pilocarpine was carried out A report on his treatment up to 1936 is given by Dax (1936) In 1938 a course of 23 injections of Cardiazol was given, which produced 16 convulsions but no improvement In 1939 he was given 18 electrical convulsions with no improvement In December, 1939, he was given a course of Ambinon injections, both with and without Pregnyl, in an effort to make his testicles descend, but there was no result

On April 2, 1941, a bilateral frontal leucotomy was performed under pentothal anæsthesia with nembutal premedication The operation was uneventful The day after the operation he was easily roused and conversed reasonably well He subsequently became irritable and difficult with his food He vomited for some days but this gradually cleared up His language was bad—rather worse than he had ever used While in bed he did not masturbate, as he had always done before when confined to bed His postoperative course was otherwise uneventful He had no recollection of the operation but says he bumped his head into a wall There was no bed wetting No definite mental improvement has yet been noted, but he is certainly not worse than he was before

CASE 7 —A woman, aged 32, with catatonia. During the past 4 years she had slowly become more and more difficult to deal with, had been in two nursing-homes and was finally admitted to Barnwood House on June 7, 1940 Since admission she had gradually become worse She was hallucinated and impulsive and finally developed homicidal tendencies and attacked two old ladies in a murderous manner because she thought that they were putting some sort of " influence " on her She was quite irrational, and without any insight

Bilateral frontal leucotomy was performed on April 2, 1941, under pentothal with nembutal premedication The postoperative course was uneventful The effects of the operation cleared up quickly although she complained of headache She was bright and cheerful No bed-wetting Rather inclined to stay in bed in the morning She has shown no real improvement, but is certainly more cheerful than she was before, and says herself she feels much better

CASE 8 —A man, aged 40, with catatonia, admitted to Barnwood House in February, 1922, since then he had slowly deteriorated An account of his early history has been given by Coleman (1931) He showed complete mental dilapidation, was quite inaccessible, hostile, noisy, violent and restless In 1938 he had a course of 10 injections of placental blood with no result This was followed by a course of 17 convulsions with cardiazol with no improvement

On April 16, 1941, a bilateral frontal leucotomy was performed under general anæsthesia with nembutal premedication His postoperative course was uneventful There was no bed wetting Some 3 weeks after the operation it was reported that he had allowed a male nurse to walk round the garden with him, a thing he had never done before, otherwise no essential change has been noted in his condition

ELECTROENCEPHALOGRAPHY

The following report on the electroencephalographic findings has been contributed by Mr Grey Walter

Immediately after the operation there is always a very large, very slow discharge, reminiscent of that following a head injury It is not restricted entirely to the area around the incision or to the frontal lobes—indeed it often involves the whole cortex, particularly while the patient is somnolent and unresponsive It is not well synchronised in the two hemispheres, resembling at times the sort of record found during deep sleep In the weeks following the operation the size of these slow potentials diminishes progressively and the source becomes limited to the frontal regions, sometimes more on one side, sometimes more on the other At this stage the patient is, of course, up and about and normally responsive In case 7 the potentials were very much smaller than in the others, when examined one month after the operation, and (though this may be a coincidence) the patient also showed less mental change after the operation than the others In case 1 even five months after the operation quite large slow potentials were found, localised entirely to the frontal lobes, and since there has been no diminution in size for the last two months it seems possible that this abnormal discharge will persist for a long time

Summary

Prefrontal leucotomy has been performed some 500 times on the Continent and in America but has so far received little attention in Great Britain Among 330 cases reported in the literature there were only 5 postoperative deaths Clinical recovery or improvement after the operation has been reported in patients who failed to respond to other methods of treatment

Bilateral prefrontal leucotomy was carried out on 8 patients (3 women and 5 men) with severe long-standing psychoses of bad prognosis

It is too early to give results of value, only 18 months having elapsed since the first operation was done, but 2 schizophrenics and 1 depressive patient have shown great improvement, 1 depressive case has shown some improvement, 3 schizophrenics have so far shown little improvement and 1 case died from myocardial fibrositis and atheromatous coronary arteries.

Bed-wetting has followed operation in 4 cases In 3 of these it has persisted sporadically for some months

The ideal type of case for operation appears to be the depressive with suicidal ideas and apprehension If we can bring peace of mind to such people we shall achieve a great deal

We wish to thank Prof F Golla of the Burden Neurological Institute for suggesting the operation to us and for valuable guidance, and Mr Wilfred Willway, surgical registrar to the Bristol Royal Infirmary, for performing the leucotomies

SURGICAL TREATMENT OF MENTAL DISEASES

J S McGregor,
M D GLASG
SENIOR ASSISTANT MEDICAL OFFICER

J R Crumbie,
M B LOND, F R C S E
VISITING SURGEON

WARLINGHAM PARK HOSPITAL

More than four years have passed since Moniz (1936) described his operation of prefrontal leucotomy for the treatment of mental disease, but the method has received little attention in this country. This may be because the attention of psychiatrists was mainly occupied with the work of Sakel (1934) and Meduna (1937) on insulin and Cardiazol Since it has now become evident that these methods are not always effective it seems justifiable to consider the merits of Moniz's operation In America the method has already been adopted with enthusiasm, and published results suggest that it offers a hope of cure when the less radical methods have failed

Moniz (1936) attempted to interrupt the frontal association fibres, first by the injection of alcohol into the prefrontal areas, and later by cutting them with an instrument of his own devising which he called a leucotome He made a trephine opening 3 cm from sagittal suture on either side, on a vertical line 3 cm in front of the tragus The dura was exposed and incised and the leucotome inserted into the white substance of the frontal poles This instrument consists of a long hollow needle with a stylet to which is attached a loop of strong wire which is made to bulge through a lateral opening in the needle when the stylet is fully inserted Rotation of the instrument causes the loop to cut a core of white substance This is repeated several times in each frontal pole

Consideration of the physiology of the frontal lobes shows that the operation is based on sound principles Injury to the frontal lobes results chiefly in alterations in behaviour, as is well exemplified by the American crowbar case Behaviour changes have also been noted after surgical removal of the frontal lobes in man and animals Distractibility, lack of restraint and boastfulness have been reported by Brickner (1936) and slowness, deliberate activity, perseverance and freedom from anxiety by Ackerly (1935) Similar changes have been observed in animals, particularly in trained monkeys and chimpanzees This work has shown that removal of the frontal areas gives rise to some form of deficiency that has been termed " intellectual " Jacobsen (1935) in his experiments with trained monkeys showed that unilateral lesions of the prefrontal areas resulted in no memory change for the tasks that had been learned Bilateral lesions in this area, however, caused definite impairment of memory for recent events, and extensive re education failed to re establish the faculty for recent memory Jacobsen concludes that these experiments show a high degree of specialisation in the associative functions in primates, in contrast with the widespread equipotentiality which has been shown to operate in the cortex of lower animals Later Jacobsen, Wolfe and Jackson (1935) showed that under experimental conditions chimpanzees might develop neuroses similar to those demonstrated by Pavlov (1927) in his animals One of these chimpanzees, an adolescent female, who had been coöperative, friendly and eager to work, was also emotional and flew into temper tantrums when she made an error in performing one of the tests These tantrums ultimately became so frequent that further experiment was almost impossible and the animal had to be rested When training was recommenced she was again cooperative but temper tantrums continued whenever she made a mistake After removal of both frontal areas a profound change appeared in the animal's reaction to the experiment, when she made a mistake she showed no emotional disturbance but quietly awaited the next trial Thus, although she made a greater number of errors than before, no suggestion of an experimental neurosis appeared To quote Jacobsen and his colleagues, " It was as if the animal had joined the happiness cult of Elder Micheaux and placed its burden on the Lord "

MODIFICATIONS OF THE MONIZ TECHNIQUE

Moniz's operation is open to the objection that it is performed blindly, and that in approaching from the upper surface of the brain it is difficult to judge the distance from the orbital surface of the cortex Consideration of these objections prompted Lyerly (1938) and Freeman (1939) to adopt modifications of Moniz's technique

Lyerly employs the same approach as Moniz but divides the fibres with a dissector under direct vision obtained with a brain speculum Freeman has modified the approach by making the two trephine openings each 5 cm above the zygoma, on a vertical line 3 cm behind the anterior orbital margin Incision of the scalp at this point reveals the coronal suture through which the trephine hole is made A hollow needle is then inserted through one opening and directed towards that of the opposite side If the ventricle is encountered the needle is redirected anteriorly Along the track of the needle is inserted a nasal elevator which is used as a blunt knife to sever the fibres of the frontal pole in both upward and downward directions

Both methods have been followed by postoperative complications such as incontinence of urine We have performed Freeman's method under post-mortem conditions, and have found it difficult to gauge the distance through which the tip of the instrument moved and to avoid damaging the orbital surface of the cortex It is also open to the objection that only an arc of white matter is cut

Freeman (1939) has applied his operation to patients with depressive states, schizophrenia and neuroses, among other conditions Of 54 patients treated 32 made a good recovery, while in 10 the result was fair, and in 9 poor He states that the first results with schizophrenics were not encouraging, but adds that the method was not at first widely applied because he decided to wait until the insulin and cardiazol treatments had been assessed He regards recent results in this type of case as favourable Lyerly (1938) has applied the method mainly to cases of involutional melancholia, and records apparent recovery in 10 of 13 cases ; 2 showed definite improvement and the remaining case recovered after a postoperative period of depression

One of the disappointments of convulsion therapy has been the frequency with which some patients relapse when treatment is discontinued This necessitates what Shepley and McGregor (1940) have referred to as maintenance treatment It is to cases of this nature that we feel this operation can most usefully be applied—that is, to patients who by their response to convulsion treatment show that they have not lost the capacity to react but are for some unknown reason unable to maintain normality

Technique adopted—We use the following technique The patient undergoes the usual preoperative preparation, and the head in the operation area is shaved and prepared with spirit on two successive days before operation Anæsthesia is obtained with Pentothal Sodium and the surgical approach described by Freeman (1939) and his collaborator is used The precise measurements are readily determined by using a rectangular metal plate, measuring 5 cm by 6 cm, perforated at a site corresponding to the proposed trephine hole (fig 1) This plate is so placed that one long and one short side are superimposed on the anterior orbital margin and zygoma respectively The site of incision of the scalp is marked through the hole in the plate A vertical incision 4 cm long is made at this point and deepened down to bone The periosteum is then reflected, and the bone having been exposed the coronal suture is identified, though it is well to point out that in many skulls this suture is not readily identified at this point A trephine opening 1 cm in diameter is now made on each side of the head These openings are so situated as to lie in front of the anterior branch of the middle meningeal artery The dura mater is exposed and picked up by a hooked needle and a small triradiate opening made in it The cerebral cortex is now revealed and the leucotome can be inserted without damage to the surface blood-vessels By means of metal callipers applied to the trephine holes the width of the brain is measured, and from this measurement the amount of white matter in each frontal pole is estimated The stop on the leucotome (figs 2 and 3) is adjusted so that its distal point will not damage the medial surface of the prefrontal cortex, and the instrument is inserted and directed towards the opposite trephine hole Suction with an ordinary syringe attached to the hollow stylet readily determines whether the anterior horn of the lateral ventricle has been entered or not Redirection of the leucotome more anteriorly is required if ventricular fluid is withdrawn The stylet is now removed and gentle traction exerted on the wire until it fits the notch on the needle The hinged portion, or blade, has now described a circle 2½ cm in diameter and has therefore divided the white matter in this area The leucotome is withdrawn and the surface of the frontal cortex washed with saline to stop any bleeding, though this is usually slight The trephine hole is so small that the dura cannot be readily sutured, but this is a slight disadvantage compared with the disadvantages of a larger trephine hole, and is disregarded The muscle is sutured and the wound closed

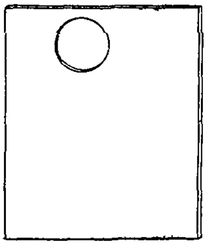

FIG 1—Rectangular metal plate for determining site of trephine openings Half natural size

CASE-HISTORIES

We have performed this operation on 4 patients, all of whom had previously undergone convulsion treatment with failure to maintain improvement, 1 was a melancholic, 2 were schizophrenics and the fourth suffered from delusional insanity In 3 of these cases the postoperative period was unattended by complications The fourth patient developed bronchopneumonia on the ninth day from which he died on the eleventh day after operation He had shown considerable mental improvement before the onset of the bronchopneumonia

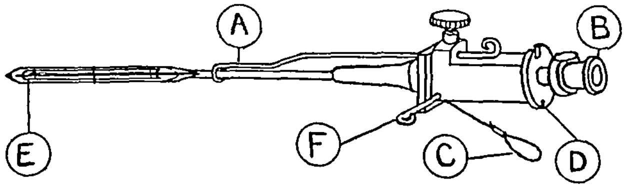

FIG 2—Leucotome, lateral view A adjustable stop, B, hollow stylet, C, traction wire, D, notch for reception of wire at limit of excursion, E, guttered cutting blade, F, guide to plane of cutting blade

CASE 1—Typical catatonic schizophrenia in a well educated woman aged 34 Duration of illness four years Admitted April, 1940, from another mental hospital where she had undergone cardiazol treatment On admission she was solitary, sullen, self absorbed and apathetic During a course of electric convulsion treatment she made a good adjustment, but quickly relapsed when treatment was discontinued Insulin treatment had a similar effect and result Examination on the day before operation showed that she had returned to her former state of self absorption and indifference In this case there was definite mental improvement from the time of recovery from the anæsthetic On the second day after operation she conversed freely and intelligently The sutures were removed on the seventh day and the patient was allowed out of bed On the ninth day she was transferred to a convalescent villa She appears to have made a complete recovery and is now awaiting discharge

CASE 2—A man, aged 47, with a history of recurring attacks of melancholia of four years' duration, characterised by depressed apprehensive anxious affect, and hypochondriacal ideas The attacks each lasted for about ten months On admission in February, 1941, he was restless, agitated and emotional He had hypochondriacal ideas and was without insight into his condition Operation was followed by depression lasting three days On the fourth day he showed a change in his behaviour foreign to his previous personality when he threw his bed-table and pillows across the ward and gave vent to aggressive language After this he steadily improved and is now well behaved, cooperative and helpful He converses readily and says he will be able to go back to work in the near future When questioned about the operation he says he feels that it has relieved him of "tension"

The third case, a catatonic schizophrenic of 7 years' duration, *shows slight improvement only*

DISCUSSION

Although it has been shown that lesions of the frontal lobes may produce a lack of restraint the mechanism by which Moniz's operation effects a cure in depressive states is not clear The procedure divides most, if not all, of the connexions between the frontal pole and the emotional centres in the thalamus, or, as recent work suggests, in the hypothalamus These centres may thus be released from cortical inhibition According to Freeman (1939) interruption of these fibres divorces imagination from feeling tone—or as he explains it to his patients, the "worry centre is disconnected" This remark is somewhat similar to that of our patient who said that the operation had relieved him of "tension"

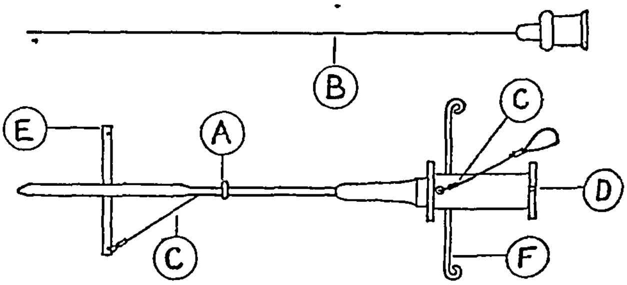

FIG 3—Leucotome from above

SUMMARY

Moniz devised an operation to divide the association fibres in the frontal lobes of the brain by means of a "leucotome" Several observers abroad have recorded improvement in mental patients after this treatment

We have treated 4 patients in this way 1 melancholic, 2 schizophrenics and 1 with delusional insanity Of these the melancholic and one schizophrenic show great mental improvement, the second schizophrenic is only slightly improved The patient with delusional insanity was much improved mentally but died from bronchopneumonia on the eleventh day after operation

The method deserves wider trial

We are indebted to Dr T P Rees, medical superintendent of Warlingham Park Hospital, for his active interest in this work, and for permission to publish this report, and to Mr J W Pearson, assistant clerk of works at the hospital, for his skill in constructing the leucotome

SULPHATHIAZOLE AND SULPHAPYRIDINE IN ACUTE GONORRHŒA

BY

H. B. JONES, M.R.C.S., MAJOR R.A.M.C.

R. W. FAIRBROTHER, D.SC., M.D. MANC., F.R.C.P., MAJOR R.A.M.C.

(*From a Military Hospital*)

SULPHONAMIDE preparations, in particular sulphapyridine, are now firmly established in the therapy of gonorrhœa. It has, however, been repeatedly observed that while in most cases early cure results from intensive administration of these drugs, some cases prove refractory (Cokkinis and McElligott 1939, Prebble 1940, Batchelor, Lees and Thomson 1940). The sulphonamide preparations vary considerably in their potency for different organisms and it is therefore important to determine if the recently introduced compound, sulphathiazole, has a greater action on the gonococcus than the earlier preparations. The value of sulphathiazole (M. & B. 760) in the treatment of acute gonorrhœa in men was compared with that of sulphapyridine, the compound used in the routine treatment of these cases. Acute cases were selected in which gonococci were found in urethral smears, and alternate patients, as far as possible, were given sulphapyridine and sulphathiazole and were kept under close daily observation until the tests for cure were satisfactory.

METHOD

The diagnosis was established in all cases by the demonstration of gonococci in urethral smears stained by Gram's and Sandiford's (1937) methods.

Group 1. sulphapyridine.—Over five days all patients received sulphapyridine, 22 g., the tablets being crushed in water (table I), 1 g. (two tablets) was given at 7 A.M., 10 A.M., 2 P.M. and 6 P.M., except on the first two days when 2 g. was given at 6 P.M. During the five days the patients were kept in bed and urethral smears were taken daily.

If the patients were free from symptoms on the sixth day and remained so until the eighth day tests for cure were carried out, and if these were satisfactory the patient was discharged after two further days observation. If the urethral discharge continued, anterior urethral irrigation with 1/10,000 potassium permanganate was given for the next three days, and afterwards, if necessary, posterior urethral irrigations were carried out until the discharge ceased, tests for cure were then performed. In persistent cases prostatic massage was used with posterior irrigations.

Group 2. sulphathiazole.—Over seven days all patients were given sulphathiazole, 22·5 g. in water (table I), the tablets again being crushed, on the first day, 1·5 g. (three tablets) was given at 8 A.M., 2 P.M. and 6 P.M. and 4·5 g. at 10 P.M. On the second, third and fourth days 1 g. was given at 10 A.M., 2 P.M. and 6 P.M., on the fifth, sixth and seventh days 0·5 g. was given at each of these times. During this first week the patients were kept in bed and urethral smears were collected daily.

TABLE I—DOSAGE IN GRAMMES

Day	*Sulphapyridine* g.	*Sulphathiazole* g.
1	5	9
2	5	3
3	4	3
4	4	3
5	4	1·5
6	—	1·5
7	—	1·5
Total	22	22·5

Tests for cure.—After the patient had been dry for three days the following tests were carried out.

1. A Kollman dilator was passed and the degree of dilatation and presence of tenderness noted, if discharge was present, a smear was prepared from it.

2. Prostatic massage and preparation of a smear. Smears were stained by Gram's and Sandiford's methods and examined for gonococci and pus cells. The presence of pus cells, even if they were only few in number, was considered at all stages to indicate persistence of infection, and treatment was continued. This practice is carried out as a routine measure and has undoubtedly reduced the incidence of relapses, which have been low in this clinic.

If tests 1 and 2 were satisfactory the patient was kept under observation for two days, after which the final tests were carried out.

3. On the third day urine was not passed in the morning until the tests were completed. Anterior urethroscopy was done, the obturator being used for massage purposes, and any abnormality noted. The four-glass test was then carried out.

(*a*) The anterior urethra was washed out with a pint of mercuric oxycyanide (1/10,000) into a conical glass, which was examined with the naked eye for the presence of threads.

(*b*) Into a second glass about an inch of urine was passed—this represented the washings from the posterior urethra and the residue from the anterior urethra.

(*c*) Procedure (*b*) was repeated into a third glass.

(*d*) Thorough prostatic and vesicular massage was carried out and a smear collected.

(*e*) The remainder of the urine was passed into a fourth glass, this represented the prostatic and vesicular washings.

Only those cases in which the urines were clear and the smears did not show pus cells or gonococci were considered cured, if satisfactory after two more days observation they were discharged from hospital. Patients returned after three months for another complete examination. The gonococcal complement-fixation test was not employed because in many cases the test never becomes positive, so that it has only a limited value.

TABLE II—DAY OF DISCHARGE FROM HOSPITAL AFTER TREATMENT

Drug	No. of cases	Discharged after 14 days	14–21 days	21 days
Sulphapyridine	51	9 (18%)	27 (54%)	14 (28%)
Sulphathiazole	30	6 (20%)	17 (57%)	7 (23%)

RESULTS

In this series, 30 cases received sulphathiazole and 51 sulphapyridine. In both groups good results were obtained, dysuria disappeared within 24–48 hours and the patients were as a rule free from discharge in two or three days. There was little difference in the end-results of the two drugs, in both groups most patients (72% with sulphapyridine and 77% with sulphathiazole) had passed the tests for cure and were discharged from hospital within three weeks (table II).

There was, however, an appreciable difference in the toxicity of the two drugs, sulphathiazole was more readily tolerated than sulphapyridine. The patients were under close observation, particularly during the stages of chemotherapy when they were kept in bed and temperatures were taken twice daily. Manifestations of intolerance were shown with both drugs (table III).

TABLE III—INCIDENCE OF SYMPTOMS OF INTOLERANCE

Symptoms	Sulphathiazole (30 cases)	Sulphapyridine (51 cases)
Nausea	3 (10%)	25 (50%)
Headache	2 (7%)	39 (78%)
Vomiting	0	2 (4%)
Pyrexia	3 (10%)	17 (34%)

These symptoms mostly persisted for two or three days, pyrexia when present was only slight, the temperature being raised to about 99° F. The more serious signs of toxicity, such as hæmaturia, cyanosis and anæmia, were not noted. Most patients returned for examination three months after treatment and no relapse has been observed.

DISCUSSION

The number of cases investigated has been small, but the trial was carried out under strictly controlled conditions such as are impracticable in civilian practice. Thus while it is not possible to draw final conclusions from the results, they are worth recording. They show that while sulphathiazole is a useful therapeutic agent in gonorrhœa (as indicated by Lloyd and Erskine 1940), it differs little in efficiency from sulphapyridine. Sulphathiazole is, however, much more readily tolerated than sulphapyridine, even though the large dose of 9 g was given on the first day of treatment toxic symptoms were seldom encountered

These findings suggest that, since the amount of sulphathiazole available is limited, in the treatment of gonorrhœa it should be reserved for the cases which show serious intolerance to other sulphonamide preparations

SUMMARY

In two strictly comparable groups of men with acute gonorrhœa sulphathiazole and sulphapyridine both proved efficient therapeutic agents and there was little to choose between the results Sulphathiazole produced fewer toxic symptoms than sulphapyridine

We wish to thank Messrs May and Baker for supplying M & B 760

IMPROVED APPARATUS FOR CONTINUOUS INTRAVENOUS ANÆSTHESIA

BY

R R MACINTOSH, D M OXFD, D A

E A PASK, M B CAMB, D A

(From the Department of Anæsthetics, University of Oxford)

IN a recent communication (*Lancet*, 1940, 2, 650) we described an apparatus for the continuous administration of intravenous anæsthetics, Further experience confirms the advantages of this route in certain operations, and we now present modifications of our original apparatus which make it simpler and safer in use The new features to which we wish to draw attention are

The use of a standard British Drug Houses or Crookes bottle of saline and/or glucose (1 in fig 1) as a reservoir for the anæsthetic solution greatly increases the applicability of this method The chosen anæsthetic is added directly to the 560 c cm (1 pint) of solution already in the bottle and the mixture is ready for use immediately after it has been well shaken

The "safety" dropper (2), which differs from the ordinary dropper in that it has a side tube, and contains a glass float the lower surface of which is ground to fit into a seating at the bottom of the dropper When there is fluid in the dropper chamber the float is kept away from its seating by its natural buoyancy, but if the chamber should become empty of fluid, as it will if the supply in the bottle is exhausted, the float seats down and the air which is under pressure in the bottle cannot escape into the patient's veins The whole dropper and float are made from thick Pyrex glass and can therefore be boiled

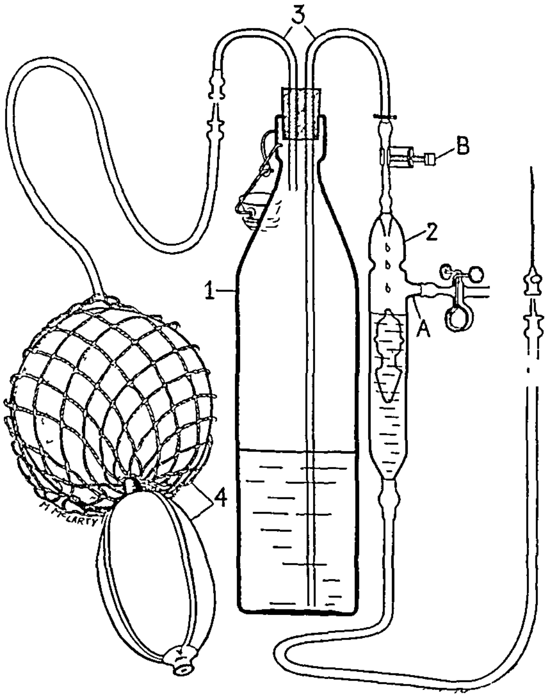

FIG 1

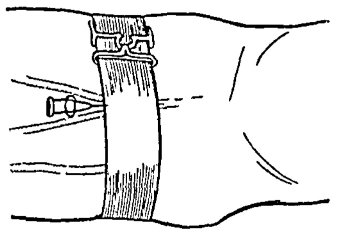

FIG 2

The rigid tubes (3), which pass through a rubber bung of correct size to fit the standard bottles, are made of stainless steel to eliminate risk of breakage

The hand bellows (4) provide sufficient pressure to maintain a rapid flow when needed, so that anæsthesia can be rapidly induced or deepened Once anæsthesia has been induced the bellows act as a reservoir of air sufficient to keep up a slow flow of anæsthetic mixture for many minutes

METHOD OF USE

A sealed standard bottle of sterile saline or glucose solution is opened and the selected anæsthetic added to it A small sterilised package containing the necessary connexions is opened and the bung firmly fixed into the neck of the bottle The hand bellows are now attached and a small pressure created within the bottle With the side tube (A) of the dropper open, fluid is allowed to run into it until the chamber is about two-thirds full, when the flow is cut off and the side tube clamped It may be necessary now to displace the float from its seating by squeezing the tube below it The remainder of the tubing is filled in the usual manner and the needle introduced into a suitable vein

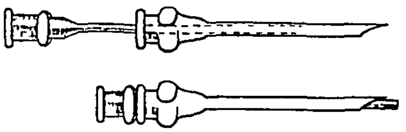

FIG 3

It has been found convenient to retain the needle in the vein by means of a narrow adjustable garter which encircles the arm, and covers that part of the needle which lies beneath the skin, but leaves free the tip of the needle within the vein (fig 2)

When a large vein is available we have used a 1 5 mm needle through which passes a blunt-ended cannula to the proximal end of which is attached the tubing from the dropper (fig 3) The cannula, at first partially withdrawn, is pushed home after the needle has been introduced into the vein The blunt end of the cannula now projects into the vein beyond the point of the needle and is not readily displaced

The screw clip (B) allows the flow to be maintained at a uniform rate, or to be varied at will between a slow drop and a continuous stream The flexibility in the rate of administration which results from adjustment of the screw clip allows a weak anæsthetic solution to be used, and thus dispenses with the necessity for a supply of an "inert" solution such as glucose or saline for keeping the needle patent when anæsthesia is deep

We have used this apparatus for various operations, including major abdominal surgery, and consider it particularly suitable for operations on the head and neck in which it is not desirable to pass an endotracheal tube For example, for ophthalmic operations, or for toilet of wounds or burns of the face, the anæsthetist can sit well away from the surgeon's field, keep a free airway by supporting the chin with the finger, and maintain an even level of light anæsthesia by adjusting the rate of flow of anæsthetic solution Anæsthetic solutions which we have administered by this method include Pentothal 0 5–1%, ether 5–7%, Avertin 1%, alcohol 33%, and various mixtures of these drugs The apparatus has also been used to give glucose and insulin in a case of diabetic coma, and should be of value as a readily transportable apparatus for administering blood

McARTHUR HERNIOPLASTY

By C R McLaughlin, M.B Camb , F R C S E
ACTING SQUADRON-LEADER, R A F V R

Although many surgeons have used the technique first described by L L McArthur[1] in 1904 for the repair of inguinal herniæ, the operation has so far received remarkably little general notice The opportunities for using this excellent procedure offered by a fairly large number of herniæ, seen at a R A F hospital during the last eight months, seem worth recording

The operation is appropriate to war-time conditions in the R.A F for several reasons First, there is a high proportion of cases of inguinal hernia in the surgical admissions to this hospital, partly as a result of frequent routine examinations by station M O s, which have revealed many herniæ of long standing in recent recruits, and partly because operation is recommended in every case of hernia Secondly, skilled man-power is limited, so that there is a demand for a quick cure which will allow the man to return to duty with the minimal delay Again, it is difficult for airmen on active service to avoid heavy manual work on their return to duty, and to advise " light duty for three months " is seldom practicable A reliable permanent cure is needed, so that it has been found wise to adopt a method of radical repair which enhances the natural strength of the inguinal canal without disturbing its essential anatomy None of the patients was over fifty, so few of the herniæ were large The objection, that in strong young adults with small herniæ any repair is an interference, is answered by the simplicity and certainty of the method, and by the fact that it shortens rather than lengthens the time in bed

TECHNIQUE AND ADVANTAGES

The McArthur operation has been carried out 90 times and (with the exception of rare cases where a Gallie *operation is indicated*) is now a routine procedure The hernias operated on included 83 indirect, 7 direct and 8 recurrent cases (direct and indirect)

The usual skin incision is made and the external oblique aponeurosis is split upwards, parallel to its fibres, for about 5 in from the external ring The sac is cleared and dealt with in the usual way Both leaves of the external oblique are then thoroughly cleared and examined If the fascia is of normal thickness a strip about ⅓ in wide is cut from the medial leaf and freed at the upper end. By using curved scissors and strong retraction this is easily managed Where the fascia has been much thinned out a rather wider strip is necessary The strip is separated downwards as far as the pubic bone, and this gives a length of 6 or 7 in , the natural fixation at the lower end is maintained, and is an economy both in time and tissue The strip is mounted on a Gallie needle, the spermatic cord is mobilised and lifted well clear of the canal, and a continuous suture begun It is important to include a good bite of conjoined tendon and of the medial point of attachment of the inguinal ligament in the first stitch The suture is continued till the internal ring fits closely round the emerging cord In large hernias it may be necessary to reinforce the upper segment of the ring, using a final fascial stitch where possible The repair is completed with an interlocking stitch and a linen fixation suture The external oblique aponeurosis is united by a continuous catgut suture, care being used to reconstruct the pillars without undue tension This last step is a departure from McArthur's original method, which involves the use of a second fascial strip to unite the divided external oblique

The normal mechanism is not altered by this operation, and the shutter effect of the internal oblique is increased to a maximum, in contrast with the results of variations of the Willys-Andrews technique The fascial suture avoids the disadvantages of catgut, which is absorbable and therefore temporary, and of silk, which is a foreign body In this connexion it may be noted that only one case in the series of 90 showed any sepsis The method is essentially simple and rapid, taking only 30 minutes in average hands It may be remarked that the tedious part of Gallie's operation is obtaining and preparing the strips, not their actual use The patient treated by McArthur's operation can return quickly to full duty In straightforward cases our routine is bed treatment 10 days , ambulatory treatment 5 days , sick leave 21 days , making a total of only five weeks

Except in older patients with massive herniæ it is possible to cut an adequate strip of fascia in almost every case, and the method can be applied equally well to direct and indirect herniæ In recurrent cases it is common to find the external oblique much scarred, but usually a strip can still be cut, and its fibrous character does not affect its utility

No recurrence has been reported among the cases in this series, but this proves nothing because too short a time has elapsed since operation Early recurrences have been often reported, however, where inadequate repair has been carried out by inferior methods On the other hand those who have used the McArthur operation longest are most positive of its reliability , and anyone who has felt at operation the extremely strong canal it produces must find it hard to see how any hernia could recur, even under severe strain

SUMMARY

A series of 90 cases of inguinal hernia treated by the McArthur fascial repair is reported

A fascial strip, cut from the external oblique, is used as a suture in the repair of the canal

The operation produces a strong result, and permits the man to return to full duty in five weeks It has special advantages under present conditions

I wish to thank the Director General of Medical Services, R A F , and the Officer Commanding this hospital for permission to publish this article , also the senior surgeon for encouragement and advice

Medical Societies

ROYAL SOCIETY OF MEDICINE

At the meeting of the Neurological Section on June 19, with Prof Geoffrey Jefferson, the president, in the chair, a paper on

Electroencephalographic Changes in Head Injuries

was read by Squadron-Leader Denis Williams He divided the changes into those occurring immediately after the injury and those seen in the chronic post-traumatic state, which might last for years after the injury Seventy-four patients had had a head injury less than 20 days before an electroencephalographic record was made, and in 10 instances a record was obtained within a few hours of the injury Three types of abnormality were encountered—the presence of large slow waves, whose period and amplitude were related to the severity of injury , absence or diminution of the normal frequencies , and, during the period of recovery shortly after the injury, outbursts of high voltage sine waves like subclinical epileptic attacks The third disturbance was found without any clinical evidence of epilepsy A series of slides and a film were used to show the progressive recovery in the e e g , which closely followed clinical improvement The e e g very often remained abnormal after clinical recovery seemed to be complete and in some of these cases recurrence of symptoms took place after the patient had returned to duty Records taken within 12 hours of a simple concussion were normal, in contrast to the gross abnormalities seen in the more severe degrees of head injury The rate of recovery of the e e g varied greatly in different subjects, but it usually paralleled the clinical recovery The disturbance was initially generalised but as improvement took place focal areas of maximal abnormality were seen These were found to coincide with areas of direct cerebral trauma by bomb fragments with depressed fractures, and with physical signs of corresponding cerebral damage, but they were also found in silent areas Careful psychological testing showed that mental changes characteristic of the frontal lobe syndrome were present with electroencephalographic changes in the frontal poles only It was concluded that in the acute post-traumatic state the e e g accurately reflected the degree of cerebral damage incurred

A total of 600 cases were used to investigate the changes in the chronic post-traumatic state In the first 325 of these cases records were kept of detailed clinical data, including progress, ultimate state of the patient, and an evaluation of the probable causation of the syndrome in each instance Half of these patients had an abnormal e e g in contrast to 3% of normal flying crews and 8% of Army personnel Even in a group of 22 patients who had sustained the head injury more than two years before an e e g was recorded, 45% showed abnormality There was a positive correlation between the length of post-traumatic amnesia and the percentage abnormality in the e e g While almost every patient with dural penetration had an abnormal e e g almost all who were free from symptoms showed no abnormality From these observations, it was concluded that in most instances an abnormal e e g after a head injury is a direct result of the organic cerebral damage and that the chronic post-traumatic syndrome of headaches, vertigo, loss of concentration, undue fatigue, mood changes and alteration in personality is usually organic in origin when the e e g is abnormal This was supported by the occurrence of a much lower percentage of abnormal records in subjects with family or personal histories of instability, epilepsy, psychopathy or psychosis In many of these the symptoms had arisen after a comparatively mild head injury

Normal e e g s in the presence of post-traumatic symptoms might be due either to full recovery of cerebral damage or to absolute destruction of cerebral substance, for complete loss of cerebral tissue did not cause the abnormal slow waves resulting from cerebral dysfunction Abnormal records were three times as common in patients discharged from the Services as a result of the symptoms as in those who returned to duty In 55% of those in whom the symptoms were thought to be organic the records were abnormal, contrasting with 33% of those with constitutional inferiority and 20% of those in whom the symptoms were thought to be due to an exogenous neurosis It seemed from these results that the e e g was an index of cerebral abnormality after head injuries, and so long as the clinical recovery and improvement in the e e g went hand in hand the outlook was good When disparity occurred it seemed that symptoms were persisting in the absence of abnormal cerebral substance, or that recovery was not complete in a patient who seemed clinically normal with an abnormal e e g In these the prognosis was less favourable

In the discussion which followed, the PRESIDENT referred to Foerster's work on the incidence of epilepsy after head injuries He said that Squadron Leader Williams's observations were in line with the clinical follow up of cases which showed that late epilepsy could not be predicted in the early stages of recovery from a head injury It seemed that some undemonstrable abnormality arose which predisposed the subject to epilepsy in later life He thought that a long-term study of the subject would be very profitable, now that the e e g was available to indicate prolonged cerebral abnormality

Dr J ALDREN TURNER asked what was the significance of the epileptiform disturbances shortly after a head injury, in relation to subsequent epilepsy, how long it took them to disappear, and whether they could be reproduced experimentally

In reply, Squadron-Leader WILLIAMS said that these epileptiform waves were so frequently seen after head injuries that they seemed to be a stage in recovery and did not necessarily have any untoward prognostic significance, although it was interesting that they were coincident with the usual time of onset of " immediate post-traumatic epilepsy " and with the periods of alteration in consciousness which C P Symonds had likened to the post-epileptic states They disappeared before the acute effects of the head injury had subsided, and could occasionally be produced afterwards by over-breathing

Reviews of Books

Principles and Practice of Diphtheria Immunisation

By J TUDOR LEWIS, M D Lond , D P H , deputy M O H for Croydon London Humphrey Milford, Oxford University Press Pp 155 8s 6d

THIS monograph has appeared when it is most needed, for with increased war-time application of prophylactic medicine, and growing public interest awakened by broadcasts and press propaganda, the immunisation campaigns of most local authorities have been intensified We seem to have escaped the toll from epidemic diphtheria which might have been expected as a result of shelter life and overcrowding, but fortunately this has not deterred many boroughs from their efforts to raise the percentage of immune children in preparation for next winter New experiences have been gained in mass immunisation against diphtheria, and this book is the result of Dr Lewis's recent experiences in Croydon It describes the methods and technique used in that borough. The historical notes and the discussion of factors influencing antibody reaction should provide a useful background for students, but the section on blood-antitoxin estimations may confuse those who have not been in recent contact with the subject The book ends with an account of the administration of a campaign among school-children, with an elaborate analysis of factors influencing the desire for immunisation, including the attitude of head teachers This and the chapter on organisation and clinic routine might well be condensed in a later edition Those working in public-health departments will find in the book a careful attempt to present up-to-date information on the routine of diphtheria immunisation in a practical and straightforward way

Science and Practice of Surgery

(7th ed) By W H C ROMANIS, M Chir Camb , F R C S , and PHILIP H MITCHINER, M S Lond , F R C S London J and A Churchill 2 vols Pp 1952 30s

THIS standard textbook has undergone complete revision and parts of it have been rewritten , it now has a section on war surgery, including the treatment of gas injuries The character of the book remains unchanged it is comprehensive, and aims at providing enough about the science of surgery for those taking the higher examinations as well as for those graduating in it, and it covers the ground well A candidate could scarcely be expected to have a more extensive theoretica knowledge than can be gleaned in these pages but he would have to supplement it with a practical operative surgical textbook in order to carry out the recommendations contained in it Specialists in different branches of surgery would no doubt find matter fo criticism but, taking everything into consideration, the authors have given a balanced and judicious account of their subject It is remarkable that the publishers have been able to maintain the quality of paper, print and binding in the midst of war without increase in price

Therapeutics of Internal Diseases

Vol III Edited by GEORGE BLUMER, M D London D Appleton Century Company Pp 738 Complete i four volumes £9 the set

THE third volume of this work deals with diseases due to parasites, physical and chemical changes i metabolism and the respiratory and circulatory systems According to the preface, diseases due to allergy, the avitaminoses, the common skin diseases and diseases of the endocrine organs should be included in this volume but they seem to have been omitted Generally speaking the sections reach a high standard but in a work of this size the reader is entitled to expect more precise details than are sometimes given—for example, a clear account of postural drainage of the bronchial tree omits the important practical point that drainage should be practised before rather than after meals It is always unavoidable that in a work with many contributors contrary opinions should occur from time to time , the scant mention of Mecholyl in the treatment of paroxysmal tachycardia in this volume contrasts with the enthusiastic account of its value in the section on pharmacology in the second volume In such cases the specialist may be able to discriminate but the general practitioner is likely to be confused More illustrations would be welcomé Why should each of the fungi have an appropriate diagram and all the metazoa and protozoa lack this distinction ?

THE LANCET

LONDON SATURDAY, JULY 5, 1941

PREFRONTAL LEUCOTOMY

THE suggestion that some cases of mental illness might benefit by division of the association fibres of the frontal lobe of the brain was first put forward by Prof EGAS MONIZ of Lisbon five years ago He argued that in such disorders the functional connexions between the cortical cells, instead of being variable, become fixed, giving rise to obsessions and delusions , and that by cutting the fibres concerned it might be possible to release the patients from their symptoms Any proposal that mental disorders should be treated surgically is bound to arouse criticism, probably not untinged with emotion The psychological and physiological hypotheses on which MONIZ founded his operation seem at first sight to be opposed to much current thought in psychological medicine, and particularly to the modern holistic view of the nervous system which has replaced earlier conceptions of localisation Our knowledge of the anatomy and physiology of the cerebrum is so scanty that we can only indicate generally the possible results of structural damage But this need not deter us from accepting any empirical treatment if it should prove valuable , indeed our ignorance should make us chary of rejecting any treatment merely because it conflicts with psychological preconceptions

That surgical interference is not devoid of risk cannot be a complete argument against it , in general medicine, if non-operative methods fail, we weigh the dangers and disadvantages of operation against those caused by the disease and choose the lesser of the two evils Insanity often carries worse consequences for the patient and his relatives and dependants than bodily disease, and many cases of insanity must still be regarded as being incurable In many of its forms mental disease is chronic, not endangering the life of the patient , but surgery is often used in the treatment of chronic bodily disorders, and few would hesitate to advise an operation with a low mortality for the relief of chronic distressing symptoms Yet in the treatment of all disease (as distinct from structural defect) surgery must be regarded to some extent as a makeshift, marking the incomplete state of our knowledge, and this is specially true of the brain

The original mental patients operated upon by MONIZ and by RIZZATTI and his colleagues were all cases with a poor or hopeless prognosis, who had failed to respond to other mothods of treatment and who could, indeed, be accepted as incurable As yet we have had no opportunity in England of judging the value of the treatment, but the latest reports from the United States seem to support the original contentions of MONIZ and the Italian school that the operation produces something like a cure in a large percentage of cases resistant to other therapeutic methods Any claim to therapeutic success in the cases reported in this issue by MCGREGOR and CRUMBIE and by HUTTON, FLEMING and FOX is naturally impossible after so short an interval , but it is noteworthy that in these two series of cases, treated entirely independently, no grossly harmful effects followed operation and there were, in some cases, signs of mental improvement LANGE has recently reviewed cases submitted to frontal lobectomy and concludes that the patients show some loss of initiative and possibly of prevision The disturbance to the adjacent nervous structures caused by the Moniz leucotomy is certainly less severe than in lobectomy but further study of leucotomised patients may reveal similar blunting of these faculties Whether this will be found too high a price to pay for the benefits claimed, and whether such benefits are lasting, remains to be seen From the evidence so far submitted it seems that the operation has most chance of being useful in cases of acute anxiety and in obsessional states

WAR FORMULARY

IT is three months since the Medical Research Council issued its War Memorandum No 3,[1] calling for economy in drugs and setting out lists of those which we can or must use fairly freely (A), those with which we must be careful (B), and those which we must give up altogether (C), but as Dr PAPPWORTH makes clear in his letter on another page the response has been disappointing Various authorities and the E M S have asked their hospitals to follow the M.R C advice, but hardly anyone seems to have taken the requests very seriously, and most practitioners have made no changes at all in their prescribing habits After a few years in practice the doctor knows what effects he may expect from certain drugs and mixtures of drugs, what are the snags to be avoided in prescribing them, and which are specially suitable for particular patients , it may take him months to become as familiar with alternatives, and he will get no thanks from his patients for making changes Moreover, some of the drugs we are asked to economise in still seem to be plentiful—bismuth and iodine, for example—and it is not encouraging to find rows of proprietary syrups in the chemists' shops when "sucrosum" and syrups appear in list B The hospital dispenser, too, who can remind the staff of the need for care sometimes takes the view that there is no point in limiting the prescription of substances of which he has a large stock The reason for economy is not always easy to grasp , we have to remember both the need for reserving all the cargo space and foreign exchange we can for food and war materials, and also, in the case of drugs made at home, that their constituents may be more useful as food or munitions, and that their manufacture and transport mean diverting labour from war industries

This is a grand opportunity for us not only to help the war effort but also to throw off unworthy traditions and rationalise our prescribing In peace-time drugs, natural and synthetic, pour into our ports from every quarter of the globe, and if some are inactive and others could well be replaced by cheaper ones who cares ? Doctors and patients have their fancies and could afford to humour them Thus the width of our world trade has widened our materia medica, and traditional medicines have come to contain ingredients whose very presence most prescribers have forgotten and few could justify Polypharmacy must always handicap progress in therapeutics by obscuring the action of active ingredients and now there can be no excuse for it We must now be in no doubt what we are prescribing and why ; when we are ordering morphia for a patient with diarrhœa we must ask ourselves whether it will really help to mix it with chloroform, hydrocyanic acid, capsicum, cannabis, peppermint, glycerin and alcohol. Simplification must be the first step towards economical prescribing, and it will lead to a fuller realisation of the true action of drugs and of how much can be done with how few. Above all, let us turn to the B.P. before the commercial circular. Not only drugs but druggists as well are scarce, let alone bottles and wrapping materials, so we must be sure before we write any prescription that there is in fact a need for medicine in this case. Placebos are very well in peace-time, and a bottle of medicine combined with reassurance may be as sound psychotherapy as any, but now we must sometimes omit the bottle and rely on the reassurance. If we do order a placebo at least let us be sure that its contents are not being brought from the ends of the earth.

---

[1] Economy in the Use of Drugs in War time H.M Stationery Office Pp 18 3d

In February the Ministry of Health announced the composition of a committee to draw up a war-time formulary, and its labours should be nearing completion. Publication of the formulary will greatly ease the task of the conscientious prescriber, and hospitals have naturally awaited its appearance instead of drawing up emergency pharmacopœias of their own. The War Formulary (W.F.) will no doubt immediately replace the National Formulary for N.H.I. prescribing, and the insurance doctor who ignores it will find himself surcharged in the ordinary way. In addition it should replace all hospital formularies, and there are already indications that the Services and local authorities will give it their blessing. In drawing up the W.F. the committee have been aiming at making the best use of available drugs and not at offering inferior substitutes, and the private practitioner will be doing the best for his patient as well as saving himself and his dispenser trouble if he uses it in his everyday work. When prescriptions are written outside the W.F. there should be some way of keeping the M.R.C. lists in the doctor's memory, or perhaps in his pocket. It could be made a rule that a chemist or hospital dispenser would make up a mixture containing something in list B only if that something was initialled by the prescriber. The unessential drugs in group C are presumably no longer imported and will slowly disappear from the market. There remains the question of proprietary medicines. Their manufacturers may deserve some reward for their foresight in laying in stores, but the Ministry of Supply cannot expect wholehearted support from doctors for saving on drugs while the M.R.C. lists are ignored by commercial firms.

A RARE SPIRIT

As WILFRED TROTTER would have been the first to remind us, it is not while grief is still poignant that an author's rank is fairly appraised. That thought may deter some who rereading his collected papers[1] and recalling the gracious personality of their author are moved to prophesy that the slender volume will live on the accessible shelf which holds "Religio Medici," ALLBUTT's FitzPatrick lectures and a selection of OSLER's essays, perhaps also HILTON on Rest and Pain, and SUTTON's lectures on Medical Pathology. Certainly, like the authors named, TROTTER could "write." He is speaking of "the case," the patient upon whom a pioneer operation was done on Nov. 25, 1884:—

> "The heresy of admitting that at the centre of this event there was a human being is possibly condoned by his short appearance before us not being without a certain tragic dignity. He was young, intelligent, courageous, and he was to die. I owe to the impeccable memory of a contemporary witness the knowledge that this young man's name was Henderson and that he was a native of Dumfries. I record this with pious satisfaction in being able to add a name to the exiguous roll of those by whose misfortune or endurance the world has directly gained. It is a strange defect in medical history to have kept so few of the names of these benefactors and to have left it to accident that we still know there existed such humble but significant people as little James Phipps and Sarah Nelmes or Alexis St. Martin. To the high professional spirit treasuring such names may seem trivial and even a little ludicrous. Let us not forget, however, that they are the names of those who have borne more substantial witness than has yet been produced by any philosopher or any theologian that all suffering is not in vain."

That TROTTER felt that emotion explains why he was beloved; that he could so express it will explain why he will be loved by those who never even saw him.

These papers cover a wide range of topics but are informed by a common purpose. It is to show that the great, the ideal doctor should understand the harmony of art (in the Hippocratic sense), science (in the laboratory sense) and philosophy (in Galen's sense) not confounding the persons nor dividing the substance of the trinity. Other great doctors before TROTTER have written memorably on the first theme. ARISTOTLE himself, so very long ago, remarked that something more than knowledge was needed for healing. Nobody has written so well on the psychological aspects of clinical medicine:—

> "The attitude of the patient approaching his doctor must always be tinged—for the most part unconsciously—with distaste and dread; its deepest desire will tend to be comfort and relief rather than cure, and its faith and expectation will be directed towards some magical exhibition of these boons. Do not let yourselves believe that however smoothly concealed by education, by reason and by confidential frankness these strong elements may be, they are ever in any circumstances altogether absent."

Great investigators before TROTTER have realised that pompous general principles impede scientific progress, as HARVEY's comment on BACON—"He writes philosophy like a Lord Chancellor"—showed. They might not have explicitly admitted what TROTTER made plain—viz., that "in general, discovery has been the result of action rather than thought" or drawn this conclusion:—

> "The historian is apt to be indignant at the obstacles to new knowledge offered by the censure of theologians and the persecution of ecclesiastics. Theologian and ecclesiastic have no doubt done their best, but the effect of their utmost zeal has been insignificant in comparison with that resulting from the conscientious use of the rational mind."

Yet the history of medicine, as TROTTER showed, bears out this diagnosis. Nobody now reads GALEN, none of his works which once gave law to the medical world will bear reading. But there are some essays, like TROTTER's, perhaps addresses to students or practitioners, neither too long nor too steeped in wholly obsolete technicality to be unreadable. One, on the proposition that the best doctor is also a philosopher, exemplifies the defect of Greek and still more of Hellenistic science. GALEN did believe in scientific research but he had a still stronger faith in principles and abstractions. His order of importance s the *logical*, the *physical*, the *ethical* , of him it was plainly true that —

---

[1] The Collected Papers of Wilfred Trotter, F.R.S. London: Humphrey Milford, Oxford University Press. Pp. 194. 10s. 6d.

> "Now facts unfortunately are not the natural diet of he mind They are laborious and often undignified to collect , they are apt to be formless, ugly, and even nasty , they dirty the fingers, they smell, and sometimes bite How different from the noble, shapely, and above all well-behaved conceptions of the mind, which are so manifestly of a higher order of reality."

That this was true of GALEN and that GALEN could ' write ' had disastrous consequences for the growth of medicine But it does not lead TROTTER to conclude that the ' theoretical speculative and rational element in the pursuit of medicine " should be rooted out On the contrary, he remarks that ' experience seems to show that a branch of knowledge strictly limited to experiment and without any kind of speculative admixture tends in time to lose its inspiration and drift into a dry and rigid orthodoxy Some such decline was perceptible in the physical sciences towards the end of the 19th century and there can be little doubt that a strict reliance on experiment alone would in the long run have a similar deadening effect on scientific medicine '

In the last of his papers which was printed a few months before his death, TROTTER approaches this problem We admit he says in effect, that reason, the *intellectus agens* of the scholastics, has in fact often produced disastrous results (indeed a modern mathematician said that ARISTOTLE, from whose creative reason the scholastics evolved their *intellectus agens*, was one of the greatest misfortunes which happened to mankind) But we must also admit (*a*) that purely experimental science tends to ultimate sterility, (*b*) that large tracts of human interests, for instance social institutions, are not directly open to experimental study and that without the application of reason "it seems probable that the ominous fatuity and confusion that mark our social and political affairs must continue to increase ' How then can we free the use of reason from its defects and retain its value ? TROTTER was already a sick man when he posed this question and his answer is partial With his usual modesty he would have said that he could not answer it, but he has indicated the direction in which a solution may be found

> "We must get rid of the disastrous belief that there is any activity of the mind corresponding with the conception of pure reason The mind has no such function All processes of reasoning however abstract are participated in and influenced by feeling We cannot separate off the reasoning process as such and set it to work in an emotional vacuum What we can do is to suspect the grosser cases of the effect of feeling and to make an appropriate correction "

Some on reading this will murmur Freud ' some will recall a teacher even greater than FREUD who defined the conditions of entrance into the kingdom of heaven There is the soul of TROTTER s teaching, intellectual humility ' The fault dear Brutus, is not in our stars but in ourselves ' We are not to throw away the instrument of reason but we are to root out the deadly sin of intellectual arrogance the fatal pride of the intelligentsia But this train of thought carries us beyond the bounds of our profession We say hail and farewell to a beloved contemporary, sure that his influence will work upon those to come after us when these times are but a memory of old unhappy, far-off things

Annotations

NERVOUS CONTROL OF THE COLON

DURING the past two years White, Verlot and Ehrentheil,[1] at the Massachusetts General Hospital, Boston have made a series of observations on the pressure changes in the rectum and lower colon in patients with disease, injury or operative lesions of the brain, spinal cord or pelvic nerves The method used was to infuse into the rectum water at the rate of about a litre in ten minutes and observe the pressures by a manometer while recording the patient s sensation of wind, desire to defæcate or cramp-like pain Normally the maximal comfortable capacity of the colon is 1500–2000 c cm , there is a basic tone which gradually relaxes with increasing amounts and this is interrupted by peristaltic contractions which last a few seconds and send the pressure up A sense of fullness is reached in the normal colon, as in the bladder, when the pressure reaches 30 cm of water , a contraction which raises the pressure above 50 cm is distinctly uncomfortable The basic tone rises steeply as the normal capacity is approached and peristaltic waves occur with increasing frequency until a state of tetanic contraction is reached , at this point fluid usually escapes round the catheter If a weak barium suspension is used and the bowel observed with X rays, the contraction peaks are seen to correspond with mass peristaltic waves Haustral segmentation movements produce no visible change in the manometer From their cases these workers conclude that the cerebral cortex normally has an inhibiting effect on the spinal reflex activity of the colon, thus increasing its storage capacity Lesions situated in the cortex or brain-stem frequently remove this inhibitory action and result in hypertonicity In spinal-cord injuries the stage of spinal shock passes relatively quickly, and a remarkable hypertonia of the colon appears soon after high injuries to the spinal cord Destruction of the cauda equina or of the sacral segments in the spinal cord produces a state of the colon in which the peristaltic rush movements are absent though haustral segmentation continues At the same time loss of sensation—of the feeling of fullness—in the lower half of the colon is complete In taboparesis and syphilis of the cord the colon shows low basic tone and feeble peristalsis and an increased capacity (3000 c cm) with greatly reduced sensation The results are comparable with those of T R Elliott[2] on the nervous control of the bladder

White and his colleagues early observed during the passage of a barium meal that the movements of the distal colon were quite different from those in its proximal part In the proximal colon there is a gradual filling of the cæcum and ascending colon with ingesta passing out of the small intestine, and this goes on until the colon is filled to beyond the hepatic flexure Haustral contractions change only the contour of the contents , at intervals, however, a great peristaltic wave occurs which sweeps the contents of the proximal colon into the sigmoid and upper rectum, and to the exterior if the anal sphincter relaxes or is out of control With training, inhibition of defæcation occurs by voluntary contraction of the anal sphincter, and this voluntary effort is absent in infancy, in unconsciousness, in disease or injury of the brain and in states of shock Further work on the lines these workers have laid down may show that in some patients with excessive sphincter action, with relaxed tone of bowel musculature, or with a combination of these arising from the persistent neglect of the defæcation call, there is an altered nervous control of the lower bowel accounting for the delay now described as dyschezia

VITAMIN C IN CORNEAL INFLAMMATION

RESEARCH in the biochemical problems of cataract[1] has shown that in this disease the lens may eventually lose all its vitamin C, while normal in the blood the level of this substance is usually low in the urine Bouton[2] suggests that the administration of ascorbic acid in certain cases of cataract is followed by visual improvement due to its effect on the ocular media, retinal vessels and optic nerve and not to any benefit it gives to the lens Further exploration of the therapeutic value of vitamin C has been made by Livingston and Walker[3] who claimed that ascorbic acid administered intravenously reduced the severity of the corneal lesions in rabbits whose eyes were subjected to a small drop of liquid mustard gas Ida Mann and Pullinger[4] were unable to confirm that ascorbic acid had any counteracting effect on mustard-gas keratitis Keith Lyle and McLean[5] have tried ascorbic acid in the treatment of 10 patients suffering from superficial punctate keratitis, dendritic corneal ulcer, scleritis with early sclerosing keratitis, postvaccinial keratitis, phlyctenular keratitis, phlyctenular "ring" ulcer, and keratitis and corneal ulceration associated with seborrhœic dermatitis In these cases there was no reason to believe that vitamin-C deficiency existed, yet although they had received routine treatment for weeks without appreciable improvement the daily administration of 500 mg of ascorbic acid (Roche) intravenously brought about a definite improvement within 48 hours In some cases all clinical signs of inflammation had subsided in 4–10 days The injections were stopped when active ocular inflammation ceased, and were followed by the administration of two 250 mg tablets of ascorbic acid t d s by mouth No local or general reaction followed the injections

PSEUDOCYESIS

THE condition of fake pregnancy was recognised in the time of Hippocrates, who reported no less than 12 cases in his practice, and many subsequent writers, including such masters as William Harvey, Mauriceau and J Y Simpson, have added their observations on the ætiology of this syndrome Perhaps two of the best known cases are those of Mary Tudor and Joanna Southcott The latter, a virgin prophetess, enjoyed a considerable following in the early nineteenth century and in 1814 announced herself with child at the age of 64 Her physician was convinced of her pregnant state by reason of the enlargement of breast and abdomen and the "sensible motion of the womb" Her disciples anxiously awaited the coming of their new messiah, but Joanna died 2 months after the date of expected delivery An autopsy was performed and no trace of the pregnancy was discovered Bivin and Klinger[6] in their monograph were able to collect 425 reported cases, adding 19 of their own The youngest patient in their series was aged 7, the oldest 79 The peak incidence from the point of view of age groups was in the 33rd year, while only 16% occurred in the menopausal age group, contrary to the usual teaching These writers noticed the tenacity with which the patients cling to their self-made diagnosis, the enthusiasm that they expend on preparations for the confinement, and the scorn that they pour on the unfortunate physician who dares to refute their claims to pregnancy They reported 3 cases who remained unconvinced that they were not pregnant for eight, nine and eighteen years Rutherford,[7] who has lately reported 7 cases seen at the Boston Lying-in Hospital between 1927 and 1940, says that the main psychological factors in the ætiology are fear, desire, hysteria, suggestion and autosuggestion The symptom complex includes menstrual disturbanc (the most common feature), enlargement of the abdomen, which may be due to fat, flatus, fæces, a full bladder hysterical spasm of the diaphragm or muscular contraction, and gastro-intestinal symptoms, of which particularly violent "fœtal" movement is the most remarkable The diagnosis is made by careful clinical observation, for the physiological changes of pregnancy in breast cervix, uterus and vagina are never faithfully copied i their entirety by pseudocyesis, there is one importan universal sign—in true pregnancy the umbilicus i everted while in false pregnancy it remains depressed Radiography and the Aschheim Zondek or Friedman test will clinch the diagnosis and provide useful concret evidence with which the physician can convince a doubting patient How difficult that may be is well illustrate by Rutherford's quotation from Simpson's "Diseases o Women" To satisfy a Scottish peasant woman in he nineteenth month of pseudocyesis that she was no gravid he anæsthetised her in the presence of her sister who, when the patient was well relaxed, felt the spin through the collapsed abdominal wall As the anæstheti wore off, the tumour reappeared and the expectan mother awoke to find herself still in possession of he tumour and her original conviction Her siste admonished her "Hauld your tongue, woman, you'r nothing in your wame for I felt your backbone mysel with my ain hand" This tip is worth rememberin when a stubborn woman defies all efforts of the physicia to convince her. But no matter with what clinical an scientific proof these patients are confronted they ma be extremely difficult to convince, so firmly roote is their belief

SULPHONAMIDES AND BONE-MARROW

PATIENTS who have received no sulphonamide drug are becoming a pathological curiosity, Wilson, in Sidney has found 20 of them, however, suffering from variou infections, and has compared the changes in the granulocytes of their bone-marrow with those in a comparabl group who had received various doses of sulphonamides The largest dose given in the second group was 159 of sulphapyridine given over 42 days to a boy age three who died from pneumococcal meningitis In th marrow of the first group toxic granules appeared in th myelocytes, and macropolycytes—large multilobulate polymorphonuclear leucocytes—were prominent, precisely similar changes appeared in the marrow of th sulphonamide treated patients—in fact, Wilson coul find no qualitative or quantitative difference between th groups Agranulocytosis has been rightly regarded a the most common of the serious toxic reactions cause by the sulphonamides Sulphonamide agranulocytos follows exactly the same clinical plan as other forms it may come on after a single small dose, but it may no appear until after a considerable amount has been give over a period of some days, or not even until a second o subsequent course of the drug is given, similar variations have been recorded in agranulocytosis due, fo instance, to amidopyrin The bone-marrow changes i agranulocytosis have been thoroughly described by Custer[2] and by Darling, Parker and Jackson[3], there i almost complete disappearance of all the granular white cells, the normoblasts are unaffected, and there are myeloblasts, lymphocytes, and plasma cells in varying proportions according to the time the disease has lasted Similar changes in the bone marrow of fatal cases of agranulocytosis have been reported by Sheckett and Price[4] (among others) in sulphanilamide cases, and by agerman and Goto[5] in sulphapyridine cases Wilson ind nothing like this in his patients , but none of them d even leucopenia and no patient with unusual sensi-ıty seems to have occurred among them Paul and marzi[6] followed the blood and bone-marrow changes ring sulphanilamide treatment, and they too were able to detect any conspicuous changes in the marrow anulocytes, even though one of their patients developed ute hæmolytic anæmia after only 15 g of sulphanil-nide, given over 8 days

The close analogy between granulocytosis due to ılphonamides and that due to other drugs suggests that is, like the others, an example of idiosyncrasy This is ertainly true of the cases occurring after a single dose, but ı a much larger group of cases agranulocytosis develops ı patients who have been taking sulphonamides for ome time Further clinical experience has confirmed 'olebrook's[7] estimate that if 25–30 g is exceeded in a ingle course of treatment the risk of agranulocytosis is nuch increased Is this due to a progressive depressing ıction of the drugs on the granulocyte-forming tissue, or s it due to a greater liability on the part of the patient o develop idiosyncrasy ? If the former, we are right in topping the administration of sulphonamides when the ranulocytes of the blood show a steady fall, and feeling hat so long as there is no such fall relative safety is ıssured But if the second explanation is correct we ıre only acting on probabilities, with the risk of agranulo-ytosis always present To answer the question we ıeed to know the changes in the bone-marrow in patients who have granulopenia and to follow these changes in ecovery or relapse Neither Wilson nor Paul and Limarzi could do this, since none of their patients showed 'eucopenia , but Wilson's observations will have shown what changes in the marrow granulocytes must be put down to the effects of concurrent infection In the meantime these negative results should not deflect us from continuing to treat every sulphonamide drug as a potential producer of agranulocytosis

PHŒNIX CITY

AFTER the seventeenth-century fire of London, as everybody knows, Christopher Wren, John Evelyn and many others devised charming plans for the new city, with capacious thoroughfares, gardens and ordered and harmonious houses Needless to say they were admired and then filed away; and London grew up as we knew it before the second fire, its narrow streets congested with raffic, its buildings for the most part undistinguished and abutting on slums, the Thames nowhere visible except from the wharves and bridges Here is another opportunity, and the London County Council with praiseworthy foresight hopes to ensure that we use it well. The Postwar Reconstruction Committee on compensation and betterment (Uthwatt committee) has published a report in which powers required to facilitate reconstruction are already being considered Something must be done to make immediate action possible when the war is over No rebuilding can take place at present without the licence of the Ministry of Works and Buildings but there is nothing to hinder owners from entering into transactions for the sale, leasing and redevelopment of their sites Owners can begin to prepare schemes and incur professional fees and expenses , and some may already be devising elaborate developments which whether they mature or not will serve to enhance the purchase value of the land Thus if the L C C has to acquire the sites after the war they would, in addition to the cost of purchase, have to cover any expenses incurred by the owner and recompense those who had gained an interest in the site The L.C C suggest that a suitable way of curbing these activities would be to prescribe any area which ought to be redeveloped as a whole Public notice of such prescription would have to be given by advertisement and by notices posted on the site The areas affected would be shown on a map and would be subject to the approval of the appropriate minister, who would also consider objections No new interest created in land in the prescribed area would be allowed to increase the purchase price to the local authority, and no building or other works would be permitted without the authority's consent The L C C consider that these powers, if granted, should operate throughout the war and for such time afterwards as might be fixed by an Order in Council , and that no compensation should be payable to owners of property because of the local authority's refusal to allow building during the period of stabilisation Similar provisions, they think, should apply to isolated properties on or near new roads, or on sites required as open spaces or for public buildings and schools Londoners may well be glad that the new vistas opened up to them by their enemies abroad are not to be closed by enemies at home

HOSTELS FOR DIFFICULT CHILDREN

CHILDREN were difficult before the war, but only those who had to deal with them—teachers, social workers, magistrates and/or parents—realised what a nuisance a difficult boy or girl could be "a sort of privileged nuisance," to turn a phrase of Sir Walter Scott. In those remote days the situation seemed to be met by a few child-guidance clinics and one or two camps run by benevolent amateurs for those who had come up against the law Evacuation accentuated the problem in two ways First, because habits of discipline were largely broken and psychological conflicts were precipitated by the uprooting of the children and their transfer to the care of people with limited power of control over them Secondly, because hostesses were unwilling to put up with unsatisfactory behaviour which parents would have prevented or condoned The fact that some billets were unsuitable also helped to bring the question to the notice of the authorities Attempts to solve the problem have been to provide hostels, to extend social welfare work among the evacuated children and to refer cases to psychiatrists, working either in child-guidance clinics or in association with local authorities Hostels for difficult children have been opened in receiving areas all over the country At present they vary greatly because trained personnel is scarce and many hostels have only a kind, motherly—and no doubt long-suffering—woman as a matron, with one or two well-meaning but untrained assistants Such an arrangement is nowhere proving satisfactory Few psychiatrists are available, and in many cases the social work has had to be carried out by people already doing a whole-time job and who have had no special training in handling difficult children Local authorities, moreover, are only just learning to take advantage of regionalisation Ideally, a hostel should serve a region, so that staffing could be adequate, children could be moved freely in a large area and proper grading of cases would be possible Psychiatric advice and treatment are essential, as the Board of Education recognise , they stipulate that proposals to send difficult children to hospitals will only be approved—under section 80 of the Education Act—when psychiatric treatment can be made available and complementary to residence in the hostel

The Mental Health Emergency Committee has taken a special interest in the provision of hostels This committee is formed from representatives of the three chief voluntary organisations for mental health—the Central Association for Mental Welfare, the Child Guidance Council, and the National Council for Mental Hygiene—and of the Association of Mental Health Workers and the Association of Psychiatric Workers Thanks to the activity of the committee, mental health workers were classed among those in reserved occupations, and a register of them, and of people suitable for work in hostels, has been compiled Workers have already been loaned to Bedford, Brighton, Caernarvonshire, Cumberland, Gloucestershire, Hampshire, Nidderdale in Yorkshire, Northampton, Oxford, Reigate, and Westmorland In several of these places the Ministry of Health has since approved the appointment of permanent workers The Child Guidance Council, moreover, is arranging a course for hostel workers The emergency committee suggest that hostels should be of the following types (*a*) sick bays for children suffering from minor physical disorders, (*b*) observation homes where difficult children can be watched for a time, (*c*) homes for those suffering from temporary emotional disturbances such as spasmodic enuresis or behaviour difficulties due to mishandling or the wrong surroundings, (*d*) homes for children with persistent psychological difficulties such as enuresis, stealing or truanting, and those of backward intelligence, or showing special types of educational retardation They suggest that whenever possible homes of type (*c*) and (*d*) should be placed in an area where psychiatric advice and treatment are available Many hostels are already doing useful work and considerable numbers of difficult children have been readjusted and returned to billets It is to be hoped that when the war is over the more satisfactory hostels will be maintained, there will always be some children who will benefit from a period of special psychiatric treatment away from home and under hostel conditions

SHORT ŒSOPHAGUS

ŒSOPHAGEAL ulcers are not uncommon and have the pathological characteristics of gastric and duodenal ulcers Discussing their relationship to the short œsophagus at a meeting of the diagnostic section of the Faculty of Radiologists on May 23, Dr A S Johnstone remarked that two conflicting views hold the field According to Briggs, Dick and Hurst, peptic ulcer of the œsophagus is almost always associated with that form of hernia of the upper part of the stomach through the diaphragm caused by congenital shortening of the œsophagus Chevalier Jackson, whose cases were in an earlier age group, denied that there is any coexisting œsophageal abnormality, and suggested that the shortening of the œsophagus in the more elderly group is acquired Hiatus hernia is a relatively common condition and fully developed in old age It is a reversible type of hernia with the cardia and a small pouch of stomach slipping freely through the hiatus, the cardiac canal being within the sac The causal factors described are loss of fat in the hiatus, loss of elasticity in the peri-œsophageal connective tissues, a stretching of the muscle bundles forming the hiatus, and increase in the intra abdominal pressure, particularly in the middle age group These herniæ are thought to be acquired on account of their frequency, their preponderance in old age and the significance of increasing intra-abdominal pressure in their production Johnstone's experience has borne this out He has met with 7 cases of chronic œsophageal ulceration and all had definite shortening of the œsophagus It is generally agreed that the congenital short œsophagus is rare, and while it has been described at all ages it seems unlikely that it is an important factor in the ætiology of chronic œsophageal ulcer This condition occurs in a large group of elderly people, numerically out of all proportion to the incidence of the hernia The most important factor in the ætiology of peptic ulceration of the œsophagus appears to be the frequent regurgitation of acid gastric juice, whose detrimental action becomes more intense when there is hyperacidity Regurgitation readily takes place with laxity of the cardia and hiatus The ulceration starts as an acute ulcer which either heals or becomes chronic It is reasonable to assume that in t course of time, during which the ulcer recurs or remai chronic, extensive infiltration will occur over a lar area This extends lengthwise in the œsophagus so tha it is likely to become shortened Contraction of t scar tissue causes the lax cardia to be dragged throu the hiatus, so that, if a reducible hernia previou existed, it now becomes irreducible There is furth support for the hypothesis of acquired shortening clinical grounds All of Johnstone's cases were in a age-group (average 64 years) later than that in whi peptic ulcers are most common, and symptoms mig reasonably be expected to develop much earlier in congenital abnormality

A SIDE-LINE OF NURSING

IN America the curriculum of the public heal nurse has lately been under discussion[1] Since 19 courses approved by the National Organisation f Public Health Nursing have been organised at universities or colleges, but the only guides to th curriculum have been the standards laid down by th organisation, and these have undergone no radic revision since they were formulated Changes hav undoubtedly been made in training to meet new deman —in psychology, social science and public health nursi administration—but it was doubtful whether the had been sufficiently far-reaching A committee h now been appointed under the chairmanship of M Katherine Tucker to determine what the public heal nurse needs to know, and the best ways of providi her with the necessary knowledge and skill T curriculum foreshadowed is to be flexible rather tha hard and fast, designed to meet present needs and the of the next four or five years It is revealing an stimulating to see what ground the committee feel t public health nurse's training should cover, she is n to have her attention focused on anatomy and phy ology, bedpans, incubation periods and the niceties hospital etiquette but on a range of living subje including maternal health, infant health, health of t preschool child, control of communicable disease, a of tuberculosis and venereal disease, care of pneumon influenza and the common cold, care of orthopædic a plastic conditions, cancer control, care of heart co ditions, of mental disorders and diseases, diabe control, care of oral conditions, and industrial hygien and the committee feel that they may have to consid other subjects—such as housing and care of the aged before they have done That the positive elemen of health, its psychological and sociological aspects, a to pervade the whole curriculum is clear from the topi under review We have no appointment over he comparable to that of the American public health nurs maybe the woman sanitary inspector, having lo become the health visitor, will finally emerge as t state registered health nurse But that time is st remote, for it will require some readjustment of standar and curriculum Meanwhile the American committee inquiry points towards that goal of social work— public health service with the accent on positive healt

Air-Marshal H E WHITTINGHAM, who has latel become director-general of the R A F medical servic has received the honour of K B E

SIR FREDERIC STILL died at Harnham Croft, Salis bury, on June 28, aged 73 Starting at Great Ormon Street his whole career had been given up to the stud of disease in children and every movement for makin their hold on life more secure had his untirin support

HOSPITALS AND THE PUBLIC HEALTH

By T Ferguson,
M.D EDIN, F.R C P E, D.P H, F.R.S E

Two major problems now face social medicine. the promotion of healthy living which implies the prevention of disease, and the prevention of incapacity from disease In the past the potential value of hospital resources has not always been fully recognised, they have not been fully developed as major instruments of constructive health policy It is significant that hospital authorities are themselves beginning to express dissatisfaction with existing conceptions: recently the chairman of managers of Glasgow Royal Infirmary said that when we ask ' Have we a really national health service ? " we must answer No He had in mind the need for a unification of health activities in which hospitals would be important but not isolated elements This reorientation of policy involves changes in administration of hospital services and changes in our conception of what hospitals can contribute to a new health order Administrative changes are necessary enough if only to permit enlightened assessment of hospital needs, to prevent unnecessary duplication of staff and equipment, and to provide a means of administering to the best advantage hospital resources as links in the chain of health services Some of the flaws in existing services result from lack of beds, others from inability to make the best use of existing beds The defects appear to lie principally in lack of diagnostic facilities, lack of what may be called finality in treatment, and lack of linkage between hospital and other major health services of the community.

THE EARLY CASE

Two types of patient compete for available hospital accommodation. those exhibiting gross pathology, which has often produced complete and long-continued disability fit only for the most transitory patching, others in whom disease is not yet so deeply established as to be inconsistent with functional recovery The claims of the former group to hospital admission are compelling enough, often it is impossible to nurse them at home and hospital authorities have no alternative but to admit them, if only on the score of policy No-one would seek to deny hospital treatment to these cases, but does their admission make the best use of limited resources ? It may well be that we need a new type of hospital to give these patients the medical and nursing care they need leaving more highly equipped hospitals to patients whose clinical condition would repay such care Patients of the " earlier " group often have to be treated hurriedly in outpatient departments where it is not always possible to exclude those early stages of disease which the hospital should treat if it is to be of real service in preventive medicine. It should be no cause for reproach that a patient admitted to the wards for investigation sometimes does not yield demonstrable pathology It may be necessary to admit a patient for exclusion of early tuberculosis though he may turn out to be free of the disease, but surely that is much better than to run the risk of missing an early, curable case and have to admit at a later stage a patient suffering from advanced tuberculosis whose prospect of ultimate recovery is slight and who may have already done considerable damage to the community Similarly, it may be desirable to isolate for diagnosis and treatment some conditions that do not normally secure admission to hospitals for infectious diseases, or to admit a patient past middle life who is losing weight, but who has—under conditions of outpatient examination—no demonstrable lesion. and even, perhaps no diagnostic change on X-ray examination, if after complete overhaul such a patient is proved to be free from malignant disease there should be satisfaction rather than regret that a hospital bed has been occupied unprofitably for a few days

The long waiting-lists of patients seeking admission to hospital inevitably exaggerate this lack of provision for diagnosis and early treatment since other more compelling—though not necessarily more promising—conditions have often to be given priority of admission As a result of the arrangement to treat Service patients in hospitals originally provided for the reception of civilian casualties (but fortunately not yet fully used for that purpose) it has been possible to treat such conditions as hernia and dyspepsia in hospital, though it is sometimes difficult to obtain similar hospital care for civilians It may be true that while a man cannot soldier with bad feet he can hirple along in civilian employment It is to be hoped that measures recently proposed for reduction of the waiting-lists of civil hospitals will make available earlier diagnostic and treatment facilities for the general community This is a type of medical care notoriously difficult for middle-class people to obtain.

LACK OF FINALITY IN TREATMENT

It is difficult to avoid the impression that from the wider public health point of view the best results are not being got from hospital treatment This does not necessarily imply criticism of the work of hospital staffs or of any particular type of hospital, there is reason to believe that some of the best of our hospitals and hospital staffs are dissatisfied with things as they stand Part of the difficulty arises from pressure on hospital resources which demands a rapid turnover of patients and, as already noted, the occupation of valuable beds by patients who have little prospect of ultimate restoration to working efficiency Even in peace-time a considerable number of the patients treated in the best of our hospitals are discharged improved to their homes and to work after the shortest possible period of hospital treatment often they return to living or working conditions that cannot fail to predispose to recurrence or aggravation of their illness There is a serious lack of convalescent accommodation and other ancillary treatment resources to bridge the gap between acute hospital treatment and restoration to working capacity The Interdepartmental Committee on rehabilitation drew attention to this leakage in relation to the aftermath of industrial accidents The observations and general lines of recommendation of that committee could be applied with profit to a wider range of states, medical and surgical alike In the care of orthopædic cases for instance, the influence of Oswestry has not yet penetrated sufficiently throughout our hospital system We are in this and other aspects of the treatment of long-continued incapacity far behind pre-war Denmark, where for 10 or 12 years there was a system of rehabilitation and absorption into useful work in which the hospital and ancillary care played a vital part

This problem of long-continued incapacity must become one of compelling importance in this country very soon for already before the war a large part of the total sickness incapacity for work of the insured population was represented by illness of over 2 years' duration, and not all of these chronic invalids were old people · a formidable number were under 45 years of age In the prevention of this long-continued incapacity, alike wasteful to the nation and demoralising to the individual, the hospital—suitably reinforced—must play an increasingly important part Despite delay in securing admission to hospital which inevitably prolongs incapacity most patients have already received some kind of inpatient or outpatient hospital treatment before they have been incapacitated for work for 3 months and it should often be possible to take more effective steps to minimise incapacity Doubtless in some cases there are inadequate notes from the family doctor to the hospital when the case is sent for overhaul, and in others there is inadequate communication by the hospital of the results of its ministrations When a doctor sends a patient to a hospital outpatient department for a single consultation he usually receives a report, but lack of coöperation often arises when the hospital undertakes treatment, inpatient or outpatient Too often the practitioner is not informed of the progress of the case, sometimes not even of the diagnosis; he may be dependent on such information as the patient himself can supply when he calls to collect certificates of incapacity This lack of coöperation may prejudice the treatment of the patient and prolong his incapacity.

Recent advances in medicine have opened up great possibilities, for example in the dietetic care and after-care of patients suffering from alimentary disorders and the nutritional anæmias, in the maintenance therapy of such conditions as diabetes and pernicious anæmia, and in the treatment of a large variety of physical and mental conditions calling for systematic rehabilitation, a group bound to assume compelling importance in the immediate future

SUPERVISION OF DIABETICS

Adequate supervision of maintenance therapy is needed and illustrates the importance of close linkage between hospital and other social agencies The cost of insulin is much less than the cost of preventable invalidity, and there is specific legal sanction for the provision of insulin and such nourishment as is necessary in necessitous cases of diabetes But strict control of insulin therapy is necessary for two reasons because indiscriminate use of insulin represents a serious danger for the patient, and because faulty insulin dosage may suffice to prolong life without relieving needless invalidity, thereby creating avoidable economic loss and hardship The cost of necessary supervision may be considerable, greater than the initial cost of the insulin, but adequate control is necessary If it is true, as many competent observers believe, that diets prescribed for diabetic patients frequently receive inadequate attention on account of lack of knowledge and supervision, then the whole basis of treatment must inevitably be undermined, for an insulin dosage can only be determined accurately if, among other factors, diet is maintained at the prescribed level, whatever that may be It is imperative to secure the cooperation of the patient, often under conditions irksome and trying, and this calls for the collective encouragement of all the forces that can be brought to bear upon him and his family—the family doctor, the suitably trained health visitor and the hospital with its dietetic department There are some occupational groups for whom it may be almost impossible to secure the necessary precision of diet—workers in domestic service for instance

WORK SUITED TO DISABILITY

This question of capacity for work in relation to nature of employment is becoming increasingly important. Of patients who have not worked for a long time, some comparatively young subjects (notably those suffering from diseases of the heart and vessels), already do not seem to offer any prospect of response to rehabilitative effort, and there are others for whom a change of occupation is clearly desirable, of whom I can cite a furnaceman, aged 39, suffering from myocarditis, a bus conductress of 25 with valvular disease of the heart; a jute worker of 36 with pulmonary fibrosis, a moulder of 17 with chronic bronchitis, a miner of 25 with a psychoneurosis, a tram driver of 34 with duodenal ulcer and gastric dilatation, a motor driver of 25 with deafness following a mastoid operation There are many occupations which involve for their workers hazards that may be particularly objectionable in the health circumstances of a particular patient To a limited extent machinery exists for preventing obvious misfits of this type, for example, in some of the silicosis-producing industries, but in many kinds of work there is not, and cannot well be, such formal machinery It should be a function of the hospital, with such specialist advice as may be necessary, to determine the risk of special dangers of this kind and to reinforce with authority efforts to induce the workmen to obtain a change of work It is important, if only in the interests of economy and manpower, that workers should be used for the kind of work they are best able to perform Since the beginning of the war there must have been thousands of patients boarded out of the Army in this country on account of such conditions as gastric and duodenal ulcer These patients can be kept symptom-free in hospital, but they frequently relapse on their return to civil life, and many of them who ought to be useful workers are incapacitated for long periods It should not be impossible by concerted effort to maintain reasonable fitness and working capacity in many of these cases, and in their aftercare the hospital can exercise an important fatherly rôle Just how best to provide the supervision and helping direction that many of these people require is a considerable administrative problem, but surely not an insuperable one in these days The almoner system as we know it does not go far enough This problem must be recognised as being a major one of social medicine, worthy of the vigorous attack of health services

REGIONALISATION

If this wider conception of hospital function is to b
adopted there must be considerable change and amplifica
tion in methods of administration long overdue. One o
the major aims of the Local Government Act of 19
was to make it possible to remove the treatment of th
sick from the sphere of the Poor Law to that of publ
health Already before the passing of the act steps ha
been taken in some enlightened parts of the country t
put hospital services on a better administrative basi
and the Committee on Scottish Health Services rightl
pointed out that for cooperation between statutory a
voluntary hospitals it is necessary to place both grou
of hospital on an equal footing, regarding hospital trea
ment as a public health function and as such dissociat
from the Poor Law In the view of the committe
hospital services should be developed by cooperation
voluntary and statutory hospitals and the publ
authorities and a definite obligation should be placed
local authorities to supplement existing hospital faciliti
if required by the central department to do so Fund
mental administrative changes of this nature are
essential prelude to any rational policy of regionalisati
and unification such as that contemplated in the com
mittee's report and more recently adumbrated by Sir
Farquhar Buzzard and the Nuffield Provincial Hospi
Trust Even with such regionalisation more beds will
necessary, in some parts of the country at all even
and for special purposes It should be possible to sal
from emergency war provision much that will go far
happier days to fill gaps in civil hospital resources a
make possible the development of comprehesive schem
of adequate provision for convalescent care, the care
the aged and the care of cripples Development of t
sort will free beds for more intensive work on early ca
and for the provision of diagnostic facilities, possib
in highly equipped diagnostic units attached to select
hospitals In this earlier work there should be clo
cooperation between clinician, radiologist and laborato
workers These steps will promote Sir James Macke
zie's conception of attack on the beginnings of disea
They should also prepare the way for the development
an active policy of rehabilitation such as that blessed
the Interdepartmental Committee, a policy whi
undoubtedly has a sphere of usefulness much wider th
the aftermath of accident, as Denmark has show
One of the principal postulates of the Rehabilitati
Committee was the importance of continuity of care
the prevention of incapacity for work Clearly
family doctor must play an important rôle in such ca
and he ought to be in closer touch with the work of
hospitals than he is, but his efforts must be supp
mented by an organised, systematic drive designed
make the benefits of hospital treatment more permane
There is need for more constructive hospital treatme
treatment that will not stop short at first-aid, valual
as that undoubtedly is Lives must necessarily be
planned That is delicate work requiring cooperati
(often difficult to gain) from the man who needs help

In securing and guiding that cooperation the hospi
and the doctor who already have won his confiden
have greatest opportunity They can, in fact, add
their other services a wider creative function and th
may well take as their text in this extended usefulne
the words of Francis Bacon, “ In sickness respect heal
principally, and in health, action ”

Ray Strachey Memorial —A committee has been set u
on the initiative of the London and National Society f
Women's Service, the Women's Employment Federation a
organisations representing women civil servants, to promo
the establishment of a memorial to the work of the la
Mrs Oliver Strachey It is proposed that this memori
should take the form of a fund for the preservation a
expansion of the Women's Service Library on women's l
and work, which is normally open in Marsham Street, Londo
S W 1, and is now temporarily carrying on its work
Oxford Mrs Strachey was one of the prime movers in t
establishment of this library She herself made constant u
of it and regarded its development as of cardinal importan
to the women of future generations Donations to the fu
should be sent to Viscount Cecil of Chelwood, c/o Miss Watt
13/14, Dartmouth Street, S W 1

In England Now

Running Commentary by Peripatetic Correspondents

N our hospital, situated as it is in the heart of the ntry, we believe firmly in the value of entertainment a therapeutic factor for patients and staff alike, and aim at securing at least two diversions of some sort ry week. In addition to these evening concerts, we ve arranged during the winter a series of Wednesday ernoon lectures, not to provide formal instruction so ich as comment on topical events in the light of their storical or geographical setting, the whole often served under some disarming title such as "The Garden of len" Occasionally, to leaven this lump, we have a cital in which the element of uplift does not profess to prominent at all, and quite a lot of amusement is often rived from these unpretentious and informal gathergs There was the learned knight who came, unshamed, to tell us funny stories, and there have been ne or two excellent song recitals, which most of us have een able to enjoy if not to appreciate fully. Recently, o wind up the winter session, we had a recital of Hebridean songs and stories of the Western Isles, rather daring venture when it is remembered that the audience was essentially a soldier one and drawn largely from English regiments The lady who gave the recital was a youthful-looking grandmother, and apparently the ritual called for the wearing of a flowing bardic robe, a terrifying, betasselled, trailing gown of green, embellished with wonderful pagan emblems, a curious mixture of thistles and acorns We are not well versed in Hebridean songs or in the technique of their delivery, but it is certain that the bardic garb is calculated first to startle and then to envelop an ordinary southern community, it creates an atmosphere at once mystic and awe-inspired

The songs themselves are extraordinary, with, to the untutored ear, one common characteristic—an underlying wail of sadness even when they profess to be records of happy days There are *sheiling* songs, love songs, mother songs, songs of sea sorrow, heroic pagan lays, clan laments, tramping songs, heroic lullabies, mystic songs, songs of death and the beyond, and labour lilts The songs of this last group are far removed from the music now employed to stimulate production in munition factories, they deal with labour of other days—milking, reaping, *spinning* and weaving, quern-grinding and cockle-gathering—simple, unsophisticated lilts, droning and dreamy, which our bard sought to illustrate by appropriate actions We were unable to provide a cow wherewith to illustrate the milking song of Skye, but nothing daunted our lady embraced one of our good tables as if it were "of the nature, substance and quality of the article demanded" and proceeded to put its legs through hypothetical milking movements

We feared for the effects of all this on our patients But they behaved in a most exemplary fashion, almost as if spellbound by their first glimpse of the golden portals of faery and the enchanted land of the west They could not have understood all that the bard had to say and sing, but even under circumstances that must have appeared to them to be quaint and unusual they preserved a philosophic calm that made us marvel As a rule they are vocal and outspoken critics, but Hebridean songs seemed to be wholly new to them and quite beyond their powers of repartee Even when milking songs were being illustrated by recourse to the mythical cow they retained a wide-eyed wonder and preserved a straightness of face that was an excellent tribute to the spell-binding quality of the performance or to Army discipline They did not even fade away as our patients so often do when exposed to the effects of something frankly beyond them, and they applauded vociferously at the end of the performance, leaving us uncertain whether they had really enjoyed it or whether they had been in some land of trance One of the songs dealt with the anguish of a calf suffering from a pain in its inside and apparently incapable of anything other than speculation about what it might eat that night, but even this appeal to the realities of life produced no obvious reaction among patients numbering quite a large proportion of sufferers from gastric or duodenal ulcer

The staff lacked the stoic qualities of their patients they appreciated, of course a fine artistic performance, but they were not so overcome as to be unable to sense the humour underlying the performance, more than once we detected an ominous twitching of the corners of the mouth and a reluctance to meet the eyes of colleagues, of patients or of the bard herself But everything passed off excellently, the patients and staff dispersed in good order and over a cup of tea we came to realise that the bard was a very human soul when divested of her bardic raiment, full of good fun and quite untouched by the gloom of her subject There must, indeed, be something beyond southern comprehension in these enchanted isles, something strangely different from the hectic bustle of our times

* * *

A friend writes "I am very reluctantly idle for the first time in my life and prepared to slay anyone who (1) talks of the joys of 'retirement' or (2) quotes 'He also serves who only stands and waits'"

How doth the recent busy bee
  Resent each idle hour,
And all the sweets of leisure he
  Implacably finds sour

How angrily he takes repose,
  How savagely observes
"I'd like to have the blood of those
  Who say 'He also serves'"

From birth to age man travels fast—
  In fact he fairly whistles
He gets a good sit down at last
  To find it is on thistles

* * *

One still sees the results of savage vaccinations—large, dirty, low-lying islands in a pool of angry red Once I was vaccinating a member of my crew in Honolulu, when an American doctor who was watching me said, "If I did that, I'd sure be in the law courts" He showed me their simple method and I have used it hundreds of times since You clean up the skin as usual, put a tiny blob of lymph in the usual place, then, with a sterile needle mounted on a cork and held almost horizontally, nearly parallel to the skin, you gently prick a tiny area under the lymph—say 1 sq mm—about a dozen times There is no blood and after wiping the surplus lymph away, you dismiss your patient incredulous He may need a protective dressing in about five days—it depends on his occupation I have done many a sleeping baby and others rarely cry The ripe result is like a pearl button on pink silk and the scar is a neat, pea-sized depression. The Americans have shown conclusively that there is no relation between the size of the vaccination and the immunity it conveys Severe vaccinations are chiefly due to secondary infection

One advantage of vaccinating by this method, especially for quarantine purposes, is that if you make a control, by putting another cluster of light intradermal pricks about an inch below the place where you are going to vaccinate, you can soon tell who is immune to smallpox For he will have a red patch at his vaccination in 24–72 hours, but you won't be able to see where your control was I did over 1000 vaccinations by this method and only two men who had not been previously vaccinated showed this immunity reaction, one, a New Zealand farmer turned sailor, had a history of cowpox, the other had a history of chickenpox in an epidemic in Northern Canada three years before, but said 'There was an old retired doctor up there who said he thought it was smallpox"

Things get lost and found again in medicine Jenner drew attention to the immunity reaction, though he didn't call it that

* * *

It was a grilling afternoon, if the Ministry of Information will allow me to say so To save a teaspoonful of petrol I had walked down from my house to the surgery With a proper sense of self-admiration and carrying a heavy stethoscope I started to walk the half-mile back which is uphill all the way Opposite the surgery there was a small girl who was bouncing a ball between her legs against a wall, catching it and bouncing it again as though her life depended on it She seemed to be working against time A few yards further on I met a small boy alternately fly-kicking and dribbling a soccer ball as fast as possible up the steep road On the grass field at the corner some local and evacuee children of both sexes were enjoying a game which appeared to be the result of a mésalliance between soccer and rugger, it was being played at a brisk pace and with desperate vigour on a sloping pitch among tussocks of grass about two feet high Arrived home I shed my coat, collar and tie and watched my infant son playing by himself with a small chair and table The game consisted in lugging the table up to the chair, sitting down on the chair for a couple of seconds, then rising and pushing over the chair and table in opposite directions, the ritual was then repeated ad libitum What a pity it is, I reflected, that all the surplus energy of children cannot in some way be harnessed (without their knowing it, of course) to the war effort

* * *

I have been interested in dreams in an amateurish sort of way ever since, as a medical student, I began to read books on modern psychology I have recorded sufficient of them to be satisfied that Mr Dunne's "Experiment with Time" has the kernel of something deeply significant, although his more elaborate expansions of his elementary theory leave me ignorantly guessing But it is the more trivial aspects of dreams which I find more interesting because I can understand these and can amuse myself by following the curious low-brow play in words which often happens, at any rate in my nocturnal adventures The other night I had a confused affair with strategy in the Middle East mixed up with hospital work, as the success of an air-borne invasion became uncomfortably obvious I was confronted with the clear fact that Hitler's secret weapon was an all-glass syringe This piece of apparatus was vividly in my thoughts as I woke As I turned over I heard the throb of foreign planes flying northwards and then—still more awake—the distant sounds of the warden's whistle in the village Suddenly the significance of the syringe was borne in upon me I had slept through the still more distant syrens and my sleeping brain had coined a silly pun syren-syringe No doubt some more sinister interpretation is possible but it is the low-brow aspect that appeals to me Scorn the humble pun as we may, as juvenile and facetious, by night the most fastidious wit of us all loses his snobbishness and sinks to the level of the pantomime comedian, or lower Odd in how many ways we can climb up and down our family tree

* * *

My omniscient gardener having been removed from the trivial task of growing food for 32 persons and put into a factory where he pours milk out of a can into a drying machine, it became necessary to find a substitute We have been fortunate enough to secure the services of the ex-head-gardener of a peer—and a pretty lofty peer at that We are, of course, a bit of a come-down for him, but he is very civil He asked permission to smoke an occasional pipe while at work and this was graciously granted "Of course," he added, "I wouldn't smoke opposite the windows where the gentry could see me" Not being able to think of a suitable reply we inclined our heads His only drawback is that he is stone deaf, which makes for one-sided conversation, but he is a good lecturer and for a lifelong teetotaller curiously broad-minded He tells me that, during the last war, he harangued a bishop in church who was denouncing the drunkenness, bastidity and licidity (sic) of the soldiers "I told 'im there weren't no bastidity nor licidity," he said "and as for drunkenness that weren't nobody's business so long as the chaps was on p'rade at the proper time I told 'im I'd pawn my shirt—and his too if I could—to buy drink for our chaps arter what they bin through and if so be as they wanted it and with that I picks up my 'at and goes out" During the last war he had five cameras 'confisticated" A man to be reckoned with

---

EPSOM COLLEGE —On June 20, at the eighty eighth annual general meeting of the college, Lord Leverhulme, the president, expressed the governors' gratitude to Dr John Fawcett for his services during the past six years as treasurer, and their regret at his resignation Surgeon Vice Admiral Sir Reginald Bond was elected treasurer in succession to Dr Fawcett

---

Letters to the Editor

SULPHONAMIDES LOCALLY

SIR,—Arising out of your leader of June 21, may I attention to the fact that the local application of anilamide is often remarkably effective in clearing impetigo and the allied superficial exudative conditions, particularly when they yield an abundant culture of hæmolytic streptococci These represent a problem of some importance in the Serv and it is to be hoped that those who have charge of will take the present opportunity to assess the v of local chemotherapy

My own observation upon a small number of cases made it quite clear that within a few days one usually get rid of the exudative phase even when t infections involve the beard or scalp, and that with change hæmolytic streptococci can no longer be from them I have usually employed a paste (kindl supplied to me for trial by British Drug Houses) con taining 30% of sulphanilamide and also cod liver oil but we do not yet know whether a much smaller centration of sulphanilamide will serve as well, whether the inclusion of cod-liver oil has been of value Nor again do we know whether in some of the staphylo coccal cases sulphathiazole, internally or externall (or both), will be helpful There is room too for in vestigation of the underlying (? metabolic) factors whic favour these troublesome infections and sometimes seen to prevent their complete cure after the streptococc infection has been eliminated

Basingstoke LEONARD COLEBROOK

SAVING ON DRUGS

SIR,—On Jan 4 you published a paper of mine which I urged the importance of economy in drugs, you strongly supported me in a leading article Af lapse of six months I have investigated the response the profession, my findings are very discouraging I three counties and one large city in which I have ma fairly extensive inquiries the hospitals are doing little nothing in the matter True the Ministry of Health h issued several circulars and distributed some copies the M R C War Memorandum No 3, but no steps hav been taken to see that the suggestions contained there are even thoughtfully considered let alone carried ou Most of the circulars are sent to medical superintenden of hospitals, most of whom are surgeons not interested prescribing The documents are filed and that is t end of them I spoke to a dispenser attached to a hos tal of over 1000 beds and he dismissed the whole idea drug economy as rubbish "As long as I can get an thing I order why should this hospital do witho anything ?" was his viewpoint, and many others wi whom I have spoken are disciples of this unpatriotic a puerile *attitude*

That circulars merely recommending but not enforci economy are insufficient was shown by Form G P 9 dealing with squill, issued by the Ministry The circul urgently requested practitioners "to refrain fro prescribing squill in all cases where its use cannot be sa to be essential" Is squill ever essential ? Practitione are advised that when they prescribe a N F formul containing squill (there are over a dozen of these) the should indicate on the prescription that squill can omitted I have interviewed twelve G P acquaintanc and only three bothered to read the circular carefully an none had ever followed its advice A busy doctor soo forgets, if he was ever aware of the fact, that, for exampl Mist diuret N F contains squill

Recently, on the same day as medical superintenden in a certain county received copies of the M R memorandum on drug economy, they were also regale with a circular from the county central purchasi *officer* stating that he had made arrangements for th buying of stocks of boric lint of B P C quality instead previous varieties The M R C pamphlet strongl condemns the use of boric lint of any type

Another glaring instance of complete neglect Ministry circulars was seen in the *British Medic Journal* for April 19 (p 584), where J R Lee advocate that a solution of iodine and potassium iodide mixed wi glycerin should be painted on abrasions and poured in inds as a routine in all air-raid casualties I suppose t as a result of his article first-aid posts and hospitals making gallons of this mixture which completely flouts M R C advice

Over six months ago Sir Wilson Jameson formed a ommittee to revise the N H I formulary Why the g delay ? The matter is urgent When the new mulary appears I urge that its use shall be made comlsory—no prescribing from the present formulary should allowed

I do not know of any large hospital, local authority or unty council which has yet compiled a war-time armacopoeia In E M S hospitals the same complancy rules Memorandum A B H 141, issued by the epartment of Health for Scotland to auxiliary and base ospitals is the most sensible official circular I have seen aragraph 4 states

"The Department have decided that from June 1, 1941, ntil further notice the drugs and preparations specified in olumns 1 and 2 of section I of the Appendix, being unnecesary under war conditions, shall not be purchased centrally or ocally for use in their hospitals Similarly, the drugs set orth in section II shall not be used in the form or for the purposes specified in column 2 and purchases, central and ocal, must be adjusted accordingly"

Why has not a similar circular been issued and similar ompulsion enforced in all E M S hospitals throughout he United Kingdom ?

The attitude of at least one county council appears to e that their total drug bill is small compared with other ospital expenditure, and therefore the problem is of minor mportance This attitude is fundamentally wrong We hould economise on drugs not for the sake primarily of aving £ *s* *d* but as an important contribution to our war ffort I advocate compulsion and immediate action

Mitcham M H PAPPWORTH

PEPTIC ULCER

SIR,—I had hoped that when the needs of war brought out the great frequency of peptic ulcer in young males some active steps would be taken to determine the factors responsible Instead the recent discussion at the Royal Society of Medicine produced no more constructive suggestion than the opener's final remark that the "establishment of a special hospital for the study of gastroduodenal disease is long overdue" Might I make the following points based on experience in the Navy and four years of study devoted almost exclusively to this problem ?

1 The clinical diagnosis of gastric or duodenal ulcer is almost worthless In 410 first barium meals on males under fifty at the Radcliffe Infirmary, where most of the physicians have at some time or other interested themselves in dyspepsia, astric ulcer was diagnosed clinically 64 times and radiogically 25 times, but only in 3 cases did clinical and X-ray diagnosis agree, and a little work with a slide rule will show that on the basis of chance there should have been 4 agreements Duodenal ulcer was diagnosed clinically 102 times and radiologically 51 times, but only in 17 cases did clinical and radiological diagnosis agree (chance expectation of agreement 13 times)

2 The radiological demonstration of lesser curve gastric niches is usually reliable, but some X-ray work is done by men whose presbyopia does not give them proper accommodation to the screen image or by men who have insufficient time to get full light adaptation and in this way small niches on the posterior wall are easily missed But in contrast to gastric ulcer, the radiological diagnosis of duodenal ulcer in this country can only be described as a farce There is no valid evidence from the post mortem room that the ratio of D U G U exceeds 1 5 1, but different radiologists working on the same material may produce ratios varying from 1 1 to 4 1 and in extreme cases up to 10 1 And unfortunately, with the present economic structure of medicine, the radiologist who produces the highest ratios and agrees with the clinicians most gets the reputation of being the cleverer man and even the cleverer radiologist

3 Granting the above facts and granting the notoriously selected nature of the ulcer population admitted to any hospital for treatment, it is obviously impossible for us to form even a rough estimate of the liability of different occupations and modes of life to produce ulceration Hence we are faced with the absurd situation that with all the huge sums spent on statistics and public health organisation peptic ulcer in young women has died out and in young men has probably enormously increased, and yet we have only guesswork and vague clinical impressions to explain the cause

4 Surely the right answer to our problems is that surgeons should notify the perforated ulcers which they suture and that we should accept that for the present as a rough guide to the incidence of ulceration—rough but better than nothing?

The logical fallacy seems embedded amongst medical scientists in the English-speaking world that because problems already solved have turned out to be simpler than was previously supposed the same applies to problems not yet solved But again and again the history of pseudoscientific theories shows that the commonest reason for accepting an erroneous explanation is this strong popular prejudice in favour of simple and single explanations where highly elaborate ones would be more appropriate As Alvarez long ago pointed out, no existing theory of peptic ulcer accounts for more than a fraction of the 20–30 anomalies in its life history and most of them can be countered by almost overwhelming arguments I believe that half the organisation of curative medicine recommended by your correspondents would become unnecessary if only valid statistics compelled us to a more hygienic mode of life in which teeth, jaws, nose, sinuses and alimentary canal developed properly and the advertisement of aperients ceased to be a major source of revenue to magazines

Oxford DENYS JENNINGS

ENDEMIC FLUOROSIS

SIR,—The problem of fluorosis, to which increasing importance is being attached, was raised from oblivion by two Swiss investigators, H Cristiani and R Gautier (*Ann Hyg publ*, *Paris*, 1925, 3, 40 210, 1926, 4, 141, 261, *C R Soc Biol Paris*, 1925, 92, 139, 946, 1276, 93, 911) A herd of cattle kept in the environment of aluminium factories and feeding on fodder exposed to gases emanating from these factories all perished within a very short time, after having suffered from a disease diagnosed by veterinary surgeons as osteomalacia, since spontaneous fractures of the bones were one of the outstanding features of the disease The investigators achieved precisely the same disease picture by feeding animals on fodder exposed experimentally to hydrofluoric and fluosilicic acids, or by administering fodder to which salts of these acids had been added The disease was so typical that they suggested for it the appropriate name of "fluorosis" The influence which cryolite (a fluorine mineral of the composition Na_3AlF_6, used in the production of aluminium) exercises upon the health of the workmen who handle it in the process of mining, sorting, packing, &c, was described by K Roholm (1937) In your issue of Feb 15 Dr Dagmar Wilson noted the effect which some of the water-supplies in this country are producing on the population of counties as widely separated as Cornwall, Somerset, Gloucester, Buckingham, Cumberland, and Durham No mention, has, however, so far been made of the clinical observations which I published in 1928 (*Franco-British med Rev* 5, 1, 61) and in a monograph entitled The Clinical Aspect of Chronic Poisoning by Aluminium and its Alloys (London, 1933) It was observed that amongst the symptoms described one in particular occurred very frequently—namely, paræsthesiæ affecting mainly the hands and more especially the fingers supplied by the dorsal cutaneous branch of the ulnar nerve, that is to say the inner side of the little finger and the adjacent sides of the ring and little fingers This last sensation was experienced on many occasions in self-observation There is to my knowledge one poison only which affects the ulnar nerve (just as lead affects the radial nerve)—namely, fluorine and its compounds, they also produce gastro-intestinal symptoms, urticaria, hypopiesis, and albuminuria, all of which were described by me as an essential part of the symptom-complex The term "fluorosis" was adopted and introduced, so far as I know, for the first time by me in this country, and the endemic nature of the poisoning was demonstrated without knowledge on my part of any earlier work on the subject by others It is to be hoped that the possibility of fluorosis will be kept in mind when dealing with cases of gastro-intestinal disturbances of obscure origin

London N W 6 LEO SPIRA

MEDICAL AID FOR CHINA

SIR,—The China Medical Aid Committee appeals for your interest and assistance to carry on its work For four years China has held out against the aggressor, and war has produced devastation and destruction, not only of homes and industries but of hospitals, with an increasing number of wounded, sick and crippled needing medical aid China, with slender medical resources, has valiantly attempted to deal with this suffering and Dr Robert Lim, director of the Chinese Red Cross, has set up numerous medical units for treating the sick and wounded and for training first-aid workers for the fighting services, but in China the number of doctors with modern training is few and in 1938 Dr Lim appealed to the western world for help.

In 1939 this committee, in cooperation with a Norwegian committee, sent out some twenty doctors who have now become heads of Red Cross units and are striving with inadequate materials and very little trained assistance to create a medical service in the front line The Chinese Red Cross, short of funds, asks us to maintain at least in part the doctors we sent out nearly two years ago The following is taken from a recent report to us

> "Moreover epidemics of typhus, typhoid and relapsing fever have taken terrifying toll In the absence of qualified people to guide the inhabitants in elementary self-protection, whole families have been wiped out and entire villages and districts have been devastated by such epidemics Infantile mortality is very high Over 70% of the population of the North West suffer from trachoma and this means thousands of blind Millions of people have not a single doctor to give advice and help the sick and wounded and there are no medicines to treat disease, prevent epidemics and protect the newborn"

The army medical service alone requires 30,000 doctors and there are but 5000 in the whole country Our contribution to this immense deficiency is small but it is appreciated Dr Lim, writing to us in March of this year, says, "Let me say how grateful we here are to all of you for still taking an interest in poor China while England is being so battered from the air It is simply splendid of the British people, and the common aim of our armies to struggle on against aggression and the example given by Britain have given the people of China a new stimulus to fight on"

Please let us have your utmost assistance and let China see that we appreciate to the full, amidst our own troubles, the great service to our cause afforded by her continued resistance to aggression Your support will be greatly appreciated Please forward donations to Dr E R C Hambly, Treharrock, Long Grove, Seer Green, Bucks

HORDER,
President, China Medical Aid Committee

ABDOMINAL ANEURYSM AND SYPHILIS

SIR,—In his criticism of my paper Dr Pappworth seems to be trying to make a case for predominance of atheromatous aneurysms, and he feels that I have not made sufficient use of the available literature I would like to take those two points in turn

I said that Nixon, Bryant, Kampmeier and Osler agree on the predominance of syphilis in abdominal aneurysms, but with only four cases of my own I did not express any personal opinion about ætiology My paper was in any case mainly intended as a clinical study, and perhaps that is why I felt that the view of these eminent clinicians was worth restatement Dr Pappworth is better pleased by a quotation from Campbell and Bedford who deduced from a "fairly comprehensive study" that 30% of abdominal aneurysms are syphilitic I should point out that more than 50% of all abdominal aneurysms known were described before the introduction of the newer, but not infallible, methods of diagnosing syphilis, of which Dr Pappworth reminds us Of these cases about 45% were under 40 years of age and 60% under 50 years of age, though I make no point of that, nor, if I were Dr Pappworth, would I make any point of the fact that Turnbull and Coombs between them only found 3 cases of abdominal aneurysm amongst 278 cases of syphilitic aortitis One might as well emphasise the fact that many patholo [illegible] seen many more consecutive cases of abdominal aortic atheroma without seeing single abdominal aneurysm

Dr Pappworth comments on the fact that I only q one "modern author" May I point out that author, Kampmeier (68 cases with at least 573 syphilitic infection) is the last and practically only authority to describe a long list of cases, and to re the past literature The 16 cases of Garland (437, syphilitic) are only briefly mentioned in a long general paper on aneurysms, while the papers of Lucke and Re and Lipschutz and Chadoff, merely mention a number abdominal aneurysms without any comment whatev If I had wished to do so, I could not have drawn a ætiological conclusions from their papers As for th series of Browne, Nunneley and Pepper, these too a not described by "modern authors," and in any ca they are included in Nixon's series which I quoted Nixon himself reviews Bryant's cases separately from h own, which he described as the "179 cases of which have collected published records"

Edgware G H JENNINGS

DEATH CERTIFICATION

SIR,—Dr Spence's article of June 21 reveals, if th facts are correct, a state of affairs in the registration deaths in Newcastle-on-Tyne which must constitute grave reflection on the medical men who provided th figures quoted and also on the registrar of births an deaths Let me quote from the first paragraph, "Nearl 10% of the deaths (25 out of 272) had taken place witho the child having received previous medical attention usually these were sudden or unexpected deaths from brief illnesses, yet an attempt had to be made to certif the cause" These doctors appear to have overlooke the gravity of attaching their signature to a documen known by them at the time to be substantially untru in fact The certificate of death states quite clearl "last seen alive by me," and the law does not permit medical practitioner to certify the death of a perso whom he has not attended in the last illness To do s constitutes an offence for which the General Medical Council may erase his name from the Medical Register

To quote again from the same paragraph "Most doctors admitted their difficulty in reaching a satisfactor diagnosis, but pleaded the necessity of putting down something which would satisfy the registrar When i doubt some used stereotyped but often irrelevant diag noses which they knew would be acceptable" Th "necessity" does not exist, for in such an event it their duty to report the death to the coroner as one th exact cause of which is obscure It is the coroner duty to establish the proper cause of death, even if t medical practitioner is satisfied that the cause is a natur one of some kind It is not for the doctor to despoil t statistics by certifying some "irrelevant diagnosis" is both stupid and dangerous for him to indulge in such practice

Guy's Hospital KEITH SIMPSON

"SCIATICA"

SIR,—The clinical picture of sciatic pain caused b pressure on one of the sciatic nerve roots by a poster protrusion of an intervertebral disc has been carefull described The essentials of the syndrome—fro descriptions based on study of an adequate number o proved cases, in which laminectomy has been performe and the protrusion removed with subsequent relief o symptoms—appear to be these —

The patient is usually an otherwise healthy man aged from 20 to 50 years In about 80% of cases there is a history of trauma, usually caused by lifting a heavy weight, but there are patients who can recollect no injury of any kind, not even a trivial one "Sciatic pain" may follow immediately, or may come after an interval, sometimes of several month The pain is felt in the buttock, in the posterior part of th thigh and the posterolateral part of the calf It is accom panied by numbness or tingling in the leg, and is aggravated coughing, by prolonged standing, and by stooping

Certain *lumbar signs* are almost constant These are, "sciatic scoliosis"—i e, a list of the lumbar spine towar or away from the affected side, limitation of movement the lumbar spine, tenderness on pressure over L4 or L

Tenderness is also almost constantly elicited by pressure on the sacroiliac ligaments, the buttock, and along the course of the sciatic nerve, on the affected side Lasègue's sign is almost always positive

Neurological signs are inconstant, they may be totally absent in 50% of cases The commonest is an absent or diminished ankle jerk. Hypotonia or atrophy of the muscles of the buttock, thigh or calf may be found, while rarely, loss of sensation can be demonstrated within the root areas of L4 and L5

The course of the malady is marked by remissions and exacerbations Pain is increased in cold, wet weather Patients in whom a protrusion has been demonstrated by lipiodol X ray examination have been cured by rest alone

In what respects does this clinical picture differ from that which Dr Walshe would attribute to a sciatic neuritis? Jevons, in his "Elementary Lessons in Logic," writes "The truth of a hypothesis altogether depends upon subsequent verification and accordance with observed facts To invent hypotheses which cannot thus be verified, or to invent them and then neglect the verification, leads to no result at all, or to fallacy" The hypothesis of an interstitial neuritis of the sciatic nerve has been invented to account for syndromes similar to that just described, chiefly because of tenderness along the course of the nerve and the inconstant neurological signs It cannot be verified I am aware that some years ago the operation of exposing and stretching the nerve had a vogue, and that this gave opportunity for naked-eye observation of the nerve covering But I am not aware that the existence of an interstitial neuritis has never been adequately demonstrated

Further, this hypothesis, advanced to account for a case of sciatic pain, is rarely in accordance with observed facts Would Dr Walshe assume the presence of a sciatic interstitial neuritis in a case in which sciatic pain followed immediately after an injury? Or in one with clear lumbar signs, especially sciatic scoliosis and tenderness on pressure over the 5th lumbar spine? Or in one where the pain is aggravated by postures which cannot possibly stretch the sciatic nerve?

There is a clinical syndrome identical with that of lumbar-disc protrusion, except that lumbar signs are absent One meets it, I should say, in about one patient in every fifty complaining of sciatic pain (and in this expression I do not include pain referred to the leg from a lesion in the region of the hip girdle—a condition which the most superficial clinical observation is sufficient to identify) Is this the picture which Dr Walshe regards as characteristic of a sciatic neuritis? If sciatic neuritis exists, its clinical distinction from pain caused by a protruded lumbar disc is of great practical importance Lumbar puncture is unreliable, and lipiodol X-ray examination impracticable, as routine diagnostic procedures

I suggest that the most helpful classification of sciatic pain should for the moment be based on clinical syndromes and not on hypothetical ætiology Excluding pain due to tuberculosis or neoplasm in the pelvic bones, and the radiating pain with which Mr Kellgren confuses the issue, there remains what most of us recognise as common or garden sciatica And this may be subdivided into

1 The syndrome of lumbar-disc protrusion Infinitely the commoner syndrome, it might be called cryptogenic sciatica type 1

2 The same, without lumbar signs It is quite rare, and might be called cryptogenic sciatica type 2 It may or may not be caused by a sciatic neuritis

London, W 1 KENNETH STONE

SIR,—What is sciatica? Surely the answer is—a group of symptoms, pain in the sciatic region being particularly prominent, which in common usage medical practitioners associate with neuritis of the sciatic nerve as well as on occasion with a variety of lumbo-sacral abnormalities

Common usage attaches the term sciatica to many painful lumbo-sacral-sciatic conditions, just as it associates such terms as "neurasthenia," "mania" and "rheumatism" with other groups of not well-differentiated symptoms

Bournemouth E L HOPEWELL-ASH

THE FUTURE OF GENERAL PRACTICE

SIR,—The letter signed by Dr H H MacWilliam to your issue of June 21 calls for an answer because it displays a grave misunderstanding of the policy of the Nuffield Provincial Hospitals Trust on the part of the author The latter is under a misapprehension in regard to the area which, it is suggested, should be included in the region of which Liverpool would be the centre

Most of those who are conversant with local conditions would agree that a large part of North Wales is served by the "key" hospitals in Liverpool, but, so far as I am aware, no decision has been reached in regard to the grouping of the North Western parts of Lancashire, Cumberland or Westmorland These matters are being discussed by representatives of the local interests concerned in this grouping, and the recognition by the trust of regional hospital councils is conditional largely on the grouping being acceptable to all such interested bodies Dr MacWilliam has overlooked the fact that each regional area contains two or more divisions to each of which there is a key hospital, municipal or voluntary, easily accessible to all parts of the division The regional grouping is mainly for consultative, coordinating and teaching purposes

Again Dr MacWilliam's description of the staffs of key hospitals dominating the lives of those attached to subordinate hospitals, "giving a small number of men the chance of brilliant careers but thwarting the development of the great majority" is entirely a figment of his imagination and quite opposed in principle to the policy of the Nuffield Trust Rather, I would suggest, does our regional scheme offer opportunities for development to many more of our profession than they have ever had in the past, if by development is meant a rise in the value of their work and of their usefulness to the community whom they serve

Oxford E FARQUHAR BUZZARD

THE PHILOSOPHICAL APPROACH

SIR,—I should like to associate myself with Dr Wright's tribute to Dr Russell Brain's most admirable essay I fear, however, that in this matter of the philosophical approach Dr Wright's misgivings are more likely to be justified than are his hopes A physician does not become a philosopher simply by stating that in his opinion there may, after all, be something in human personality which cannot be fully explored and assessed by the methods of organic neurology on the one hand, or of orthodox "scientific" psychotherapy on the other When he announces this conclusion as a startling new discovery, he makes himself slightly ridiculous, and he often reveals with refreshing naïvete that his conception of scientific method is as pleasantly vague as his notion of what constitutes philosophy

By all means let Dr Russell Brain's essay be read at inaugural lectures on psychiatry, as Dr Wright suggests, but also let no such lecture be given save by a physician who has studied some such work as, for example, McNeile Dixon's "The Human Situation" In that truly noble book we may read "Science and materialism are one, and cannot live apart Matter talks matter, and science knows no other language Suppose an independent world of thought, science has no means for its exploration To admit a world beyond her powers of inspection would be to sign her own death warrant . . She files and oils the old key, and clings resolutely to the hope that some day it will be found to turn the wards"

London, W.1 HENRY YELLOWLEES

THE NATIONAL LOAF

SIR,—Sir Ernest Graham-Little complains that an important aspect of the fortified loaf remains obscure—namely, the one relating to calcium The *Daily Mail* of June 25 contains what is apparently an official announcement to the effect that the fortified flour at present does not contain added calcium, and that it is doubtful whether calcium will be added later It has been stated in a memo of the Medical Research Council published a few weeks ago that it has become necessary to add calcium to flour because of the unsatisfactory condition of the bones of part of the population Well, let them produce (say) a dozen adults suffering from this disease and exhibit them at the Royal Society of Medicine

In a memo published by the council in your issue of June 28 it is stated that the present emergency requires the addition of calcium to bread No scintilla of evidence exists for this pronouncement

The original proposal was based on evidence derived from pre-war data, and this proposal was not intended to be a war measure I should like to know on what authority it is stated that the added calcium can do no harm in any type of disease It is not enough to say that there is no evidence that added calcium can do no injury in any type of disease , the responsible authorities must make *sure* that chalk can effect no injury in any circumstances They must prove this , for forty million people cannot be used as experimental rabbits All available evidence suggests, too, that calcium in these circumstances is ineffective without the addition of vitamin D

I know that the assertion of the M R C that added calcium can do no harm in any type of disease is contrary to the actual facts If there is to be compulsory chalk swallowing today, there may be other substances which cranks may force on us in the future Public interest demands that an exhaustive inquiry into the matter should be instituted by a board comprising men familiar with the different aspects of the problem physiologists, physicians, pathologists, biochemists, food experts, pharmacologists Members of this body ought to have no connexion with the M R C or the Food Ministry The inquiry should be open and detailed evidence published I trust the Government proposals will not become effective until the pronouncement of such a body becomes available

Liverpool I HARRIS

A RE-DRAFT OF THE DRUG BILL

SIR,—In an annotation last week you appear to have welcomed, without qualification, the disclosure of formulæ of proprietary medicines, on the ground that it was an anomaly that grocers were to be allowed to sell recommended medicines of unknown composition and not those of declared composition

Whilst this does at first sight seem an anomaly, it is clearly not so, because the grocer sells these articles as commodities at the present time, knowing nothing of their composition and being unable, by reason of lack of knowledge of their contents, to do more than sell them on the demand created by advertising When, and if, disclosure is the rule with these medicines, it will be found that grocers assume a knowledge of what they are selling, and commence recommending or " prescribing " the medicines There are firms who will supply them with the requisite assistance in this respect , hence a tremendous increase in counter prescribing and self-medication, such as doctors have not hitherto had to experience, is a very likely result of this apparently sensible requirement, unless some other restriction on the sale of these preparations is included in the bill

G A MALLINSON,
Secretary, National Pharmaceutical Union

MEDICAL PLANNING RESEARCH

SIR,—Medical students are naturally profoundly interested in the form that the medicine of the future is to assume, and welcome the opportunity to play an active part in shaping this future We feel that the section of the research in which we can be most useful is medical education, since what we lose in perspective we gain in familiarity It may interest your readers to know that the British Medical Students Association has been invited by the chairman of the B M A Planning Commission to submit a memo on medical education for the consideration of the commission The production of this memo is to be the chief subject for discussion at the B M S A council meeting to be held at 3, King's Parade, Cambridge, on July 5 and 6 It may not be too late to add that all medical students are welcome at this meeting, and any who are unable to be present are invited to submit proposals in writing to me at that address

Cambridge CECILY M TINKER,
Hon Sec B M S A

MISTY WINDOWS

SIR,—If gas attacks come we may have difficulty in maintaining clear vision through the windows of our respirators Some ten years back Mr Bedford Russell told me, apropos laryngeal mirrors, that any propne toothpaste makes as efficient an anti-dimming prepa tion as it is possible to get A little of the paste sho be smeared on and then polished off It works well wi gas-mask windows, and incidentally with motor-c windscreens as well

From the Annual Reports

RUTLAND

Dr Christopher Rolleston's report on school children of Rutland is brief but breezy Rutland is one of the smallest education authorities in England—an advantag to the school medical officer because it allows him tim and opportunity to recognise slight departures from full health Much of the criticism of evacuated children by medical officers in receiving areas, though just, did not allow for the large numbers of children the officers of great cities have to keep under observation Rutland received children, mainly from London, of whom Dr Rolleston examined 289 He found their nutrition to be good only 1 was of subnormal, and 5 of poor nutrition There were 4 cases of obesity and 1 of tuberculous glands He is a strong advocate of tonsillectomy and records " with considerable pleasure" that 23 out of 205 pupils routinely examined had had the operation performed , 19 other children are in need of operation In the whole group 259 teeth had been filled " No doubt this redounds to the manual dexterity of the dental profession," he says, " but it appears to me that this highly specialised portion of the profession might contribute something to the causation of this condition Most of the work in this direction has been published by medical men and physiologists, and their results tend to prove that the prevention of caries rests with the treatment of pregnant women " Dr Sim Wallace and other dentists will have something to say about this statement Dr Rolleston mentions the rapid cure of cases of persistent suppuration of the scalp by sulphamethylthiazole

BOOTLE

Bootle was on the first list of towns to be evacuated and its school work was much hampered by the fro and-t movement of children in the first period of the war I June, 1940, the number on the roll of elementary school in Bootle was 9226 In Southport, to which the childre should have been evacuated, there were only 892 Bootl children. The number of school-children evacuated i September, 1939, was 1346 In medical inspection 29 cases of inflammatory conditions of the external eye wer detected, of which 23 only were treated by the ophtha mic surgeon , there was no case of phlyctenular co junctivitis or corneal ulceration, and it is a reasonabl presumption that most of the cases were minor forms o infectious conjunctivitis Dr E T H Wood record an incidence of 0 9% of suppurative ear discharg among children routinely inspected and says tha " this figure continues the curve of steady decrease i number since the system of registering and followin up aural defects was instituted in 1930 " In forme years otorrhœa was the most frequent cause of rejectio of recruits for the Army, and one of the commones defects of school-children The remarkable reductio in its frequency in the past 15 years has been due mainl to the intensive drive against it, but has probably bee helped by the mildness of scarlet fever and measle and by improved nutrition

WREXHAM

Dr T P Edwards reports that among 3626 school children, 406 had treatment for skin diseases, of whom 93 had impetigo, 76 scabies and 14 ringworm Scabies has generally been increasing in the last four years, more rapidly since the war started , impetigo always has been highly prevalent in school-children and shows no sign of diminishing Two cases of definite pulmonary tuberculosis were discovered in children inspected last year When school medical inspection started we expected to find many cases of phthisis, but it soon appeared that this manifestation of tuberculosis is rare at the school age , of late years, however, with bette pervision of contacts and improved means of early gnosis, we are finding early tuberculosis of the lungs ore often in young children Formerly a positive gnosis of pulmonary tuberculosis in a child was ntamount to a death warrant, but cases detected early w usually do very well Dr Edwards calls attention the epidemic of cerebrospinal fever which struck rexham severely in the winter of 1939–40, but makes mention of any sequels (the chief of which from the hool medical point of view is deafness)

CROYDON

Dr Oscar Holden in his school report for 1939 remarks n the low incidence of infectious disease, both in schoolhildren remaining in Croydon, and in Croydon children vacuated to reception areas "A completely satisfacory explanation is not yet available," he says, "but ndoubtedly the closure of schools and the curtailment f school time appears to have been an important factor" ost school medical officers call attention to this unexectedly low incidence of infectious disease in 1939–40 nd many attribute it to school closure Dr Percy tocks of the Registrar-General's office has shown that here is some statistical evidence to support this explanaon, but if it is the true one the low incidence should erely have proved only temporary and have been ollowed by epidemic prevalence when the schools eopened, and this has not occurred yet In the last war, hen there was no school closure or dispersal, the ehaviour of the endemic infections was as follows carlet fever rose in attack-rate per 1000 population from 9 in 1911 to 4 47 in 1914, and then sank to 1 44 in 1918 rise to 2 29 in 1919, diphtheria rose from 1 24 in 1912 1 61 in 1914 then declined to 1 28 in 1917 to rise again 1918 to 1 31, enteric, after being steady for three ears, fell continuously from 23 per 100,000 population n 1914 to 9 in 1919, measles mortality (incidence igures are not available) fell to 0 247 in 1914, rose to 46 in 1915, fell to 0 15 in 1916, rose to 0 38 in 1917, and hen fell to reach the record low rate of 0 098 in 1919, erebrospinal fever *deaths* rose from 163 in 1913 (the ighest number for many years) to 194 in 1914 and then umped to 1974 in 1915, after which they declined, but ever fell again to the low levels usual before 1913, nfluenza deaths remained between 5000 and 10,000 nnually from 1913 to 1917, but in 1918 rose to 112,329 erebrospinal fever is the only epidemic disease which ppears to be directly associated with modern wars from he time of their declaration

The rheumatism clinic of Croydon shows a reduction n numbers of cases referred to it, which in part must be ttributed to evacuation, but this clinic, as do others, hows a steady decrease of incidence, and still more of everity, in child rheumatism during recent years Dr R Millar, who is in charge, classifies his new cases into hree groups mild and potential, definitely active, nd definitely quiescent In the three years 1937–39, he percentage in the second group fell from 14 5 to 11 1, whereas in the third group it rose from 9 5 to 24 1

NORFOLK

Dr T Ruddock-West in his school report for 1939 ells us that on the last day of the year there were 36,783 Norfolk children and 10,707 evacuees on the chool registers The percentage of children found by outine examination to be in need of treatment other han for defects of nutrition, uncleanliness and dental isease, was 10 79 There were great increases in cabies, impetigo and verminous heads, increase in these onditions was general throughout the country Unlike nfectious fevers they appear to have been fostered by chool closure and dispersal This might have been xpected, since children have least direct contact when hey are in school A survey of Norfolk children dislosed 973 with suspected mental defects, of whom 6 were diots, 52 imbeciles, 19 uneducable feeble-minded, 325 ducable feeble-minded and the remainder—except for ne insane child—dull, or backward, or unstable

Infectious Disease in England and Wales

WEEK ENDED JUNE 21

Notifications —The following cases of infectious disease ere notified during the week smallpox, 0, scarlet ever, 955, whooping-cough, 4837, diphtheria, 919, enteric fever, 127, measles (excluding rubella), 8958, pneumonia (primary or influenzal), 668, puerperal pyrexia, 116, cerebrospinal fever, 211, poliomyelitis, 9, polio-encephalitis, 0, encephalitis lethargica, 6, dysentery, 113, ophthalmia neonatorum, 75 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on June 18 was 1607, including scarlet fever 187 diphtheria, 314 measles, 282, whooping cough, 457, enteritis, 13, chicken pox, 81, erysipelas, 36 mumps, 7, poliomyelitis, 1, dysentery, 3, cerebrospinal fever, 47, puerperal sepsis, 9, enteric fevers 12, german measles, 14, glandular fever, 1, other diseases (non infectious) 60, not yet diagnosed, 83

Deaths —In 126 great towns there was no death from scarlet fever, 2 (0) from enteric fever, 34 (3) from whooping-cough, 10 (0) from measles, 24 (0) from diphtheria, 32 (1) from diarrhœa and enteritis under 2 years, and 6 (0) from influenza The figures in parentheses are those for London itself

Ilford and Nottingham each reported a fatal case of enteric fever There were 4 deaths from diphtheria at Liverpool Fatal cases of whooping cough were scattered over 24 great towns, Liverpool reporting 5

The number of stillbirths notified during the week was 213 (corresponding to a rate of 44 per thousand total births), including 17 in London

---

Parliament

Pharmacy and Medicines Bill

Mr Ernest Brown, the minister of health, introduced this Bill *to amend the Pharmacy and Poisons Act 1933,* and to prohibit certain advertisements relating to medical matters and to amend the law relating to medicines

QUESTION TIME

Fortified White Flour

Mr R J G Boothby asked the Parliamentary Secretary to the Ministry of Food when it was proposed to commence the fortification of white flour and when this process was likely to be completed —Major Lloyd George replied Flour millers supplying flour to the whole of South Wales have commenced the fortification of their deliveries of white flour with vitamin B_1 The area over which fortified white flour will be delivered will be extended rapidly with the increase of supplies of vitamin B_1 but I am not able to state precisely when it will be possible to fortify all white flour delivered throughout the country

National Milk Scheme

In answer to a further question from Mr Boothby, Major Lloyd George said The approximate number of persons now benefiting under the National Milk Scheme is 3,050,000 The annual cost of the scheme to the Exchequer is £13,500,000 including approximately £600,000 for administrative expenses

Clothing Coupons

Mr C T Culverwell asked the President of the Board of Trade whether he would allow the white drill coats used by medical and dental students, nurses, workers in laboratories, shop assistants and others to be sold without coupons —Mr O Lyttelton replied The suggestion is being considered as part of the general question of special occupational needs, on which discussions are proceeding The principle is agreed, but it is a question of securing a definition

Adjustment of Sectors in London E H S

The extent to which effect can be given at the present time to the Select Committee's recommendations on the London sectors is being considered in conjunction with the several officers and bodies concerned Certain rearrangements have already been made which will reduce the number of sectors by one as from next week (Miss F Horsbrugh replying to Sir Francis Fremantle)

Mental Health among Children

Sir Francis Fremantle asked the Minister of Health what arrangements were made for mental health work amongst evacuated children and in bombed areas, and whether assistance would be given to the Mental Health Emergency Committee for this work —Miss Horsbrugh replied Mental health work amongst children is a normal development of the mental health services and in particular of the school medical services with which child guidance clinics are associated in many areas A number of hostels have been established for difficult children in reception areas, and it is desirable that in every region some of these hostels should be earmarked for children requiring mental treatment and should be associated where practicable with child guidance clinics A grant from Exchequer funds was made to the Mental Health Emergency Committee in respect of the year ended March 31 last and application for a further grant is now under consideration

Amendment of Notifications

Mr W Leach asked the Minister whether table 28 in the Registrar General's report for the year 1938 referred only to cases of infectious diseases notified, or whether the figures had been corrected to allow for wrong diagnosis, in view of the fact that from 20 to 45% of cases notified as diphtheria were subsequently re diagnosed —Mr E Brown replied The record of notifications appearing in the Registrar-General's publication is based on returns received weekly from each local medical officer of health The form on which the weekly return is made includes a space for the amendment of provisional or erroneous notifications in previous returns The published record relates to notifications as amended under this arrangement In practice the number of corrections brought to notice in this way is relatively small and is in no way indicative of the scale of re diagnosis suggested in the question

Re-examination of Recruits

Mr G Mathers asked the Minister of Labour if men called up and medically examined, but who had had their posting to the armed forces deferred for a period, would be given a further medical examination before having to report for service —Mr Ernest Bevin replied If re examination after a specified period were to be prescribed it would not be administratively practicable to confine it to men about to be called up and a great amount of trouble and expense would be caused to no purpose I propose, therefore, to arrange for men who have been medically examined to be informed that they should let the ministry know if subsequently they think that there has been any deterioration in their physical condition, so that a further medical examination may be held in such cases This arrangement will cover cases that would not be included in a system of automatic re examination after a fixed period

BIRTHDAY HONOURS

The honours list for members of the Services issued on July 1 contains the following names of members of the medical profession —

K B E

Air Marshal Harold Edward Whittingham, C B E, M B Glasg, F R C P, D P H, D T M & H, K H P, R A F
Director general of R A F medical services

C B

Surgeon Rear Admiral Cyril Verity Griffiths, D S O, M R C S, K H P, R N
Major General Robert Cecil Priest, M D Camb, F R C P, D T M & H, K H P, A M S
Consulting physician to the British Army and B E F, professor of tropical medicine at the Royal Army Medical College

O B E

Major Abani Mohan Chaudhuri, M B Calcutta, F R C S, I M S
Acting Captain Edward Cawdron Cordeaux, D S O, M B Lond, R N
Surgeon Lieut Commander Ronald Grant Dingwall, M B Aberd, R N
Major (temporary Lieut Colonel) William Ralston Duncan Hamilton, M B Glasg, R A M C
Surgeon Commander Thomas Madill, M B Dubl, R N

M B E

Lieutenant (temporary Major) George Jameson Carr, M B Edin, R A M C

A F C

Flight Lieutenant William Kilpatrick Stewart, M B Glasg, R A F V R

Messrs E and S Livingstone inform us that their binders' premises have been destroyed by fire The whole of the contents, which included all work in progress and a large reserve of bound stock of their publications, have been lost They are doing everything in their power to replace the more important books, but some of these will be out of print for a time, and medical practitioners interested in their publications are meanwhile asked to make allowances

Obituary

DAVID WARDROP

M R C S, F R C S E, MAJOR R A M C

Gale and Polden

Major Wardrop, killed by enemy air action in th Near East when acting as surgical specialist to general hospital, was only son of Mr David Wardrop, consulting surgeon to the throat department of the Hospital of St Cross, Rugby David junior went t school at Lawrence Sheri and then on to Rugby, whe he excelled at football H studied medicine at Birmingham and at St Mary's, qualifying in 1928 and takin the Edinburgh surgical fellowship three years later after house-appointments and a surgical registrarship at the Birmingham General Hospital In 1932 he married Joyce, daughter of Dr Arnold Chaning Pearce, and started practice in Wellingborough, moving thence in 1935 to Seaford "His was a particularly happy nature," writes a colleague, "but, while enjoying life to the full, he was always conscious of his duties to others When at Rugby, he played three-quarter for the school XV and later he represented his university and county He was a keen golfer and was never unduly downcast by finding his ball in an awkward lie In fact, David was an all-round sportsman In his work as in his play he put his best foot forward, and in addition to being in a busy general practice he was showing considerable skill as a general surgeon "

Major Wardrop leaves his widow with three children

DONALD STARR

M B MANC, CAPTAIN R A M C

Captain Starr, who has lost his life on active service in the Middle East, was only son of Mr James Starr of Wigan Educated at the grammar school there and at Manchester he qualified M B, B Ch in 1926 He was house-surgeon at the Royal Infirmary before gratifying his love of travel by five years' service with the White Star Line He was then medical officer for nine years at the Kent mental hospital, Chartham Down On the outbreak of war he applied at once for a commission in the R A M C Loyalty, patriotism and devotion to duty were outstanding amongst his qualities, and his constant cheerfulness and optimism endeared him to his friends

ADAM BROWN KELLY

M D, D SC, LL D GLASG, F R F P S

Dr Brown Kelly, who died on June 25 at his home in Helensburgh, aged 76, was the son of Adam Lawson Kelly, who practised in Carlton Place, Glasgow Brown Kelly graduated at Glasgow University both in science and medicine in the 'eighties, and afterwards made a special study of diseases of the ear, nose and throat In addition to his practice in Glasgow he was for many years surgeon for his specialty to the Victoria Infirmary He had been president of the section of laryngology R S M, and in 1926 he was Semon lecturer in the Uni versity of London He edited the section on laryngo logy and rhinology in the Transactions of the 17th Inter national Medical Congress In 1932 his university conferred on him the honorary degree of LL D in recognition of his services to medicine and to the medica school. His son Derek, who is assistant surgeon in his father's old department at the Victoria Infirmary s at present serving with the Royal Navy Dr Brown Kelly is also survived by his wife and a daughter

LYON RAMSAY BLAIR

M D ST AND , SURGEON-LIEUTENANT, R N V R.

Dr L R Blair, who is "presumed lost ' by the sinking of the *Manistee*, was born at Dunblane in 1907 Within six months he was taken to South Africa, where he spent the first nine years of his life When his parents returned to Scotland, he attended the Morgan Academy, Dundee He graduated from the University of St Andrews in 1931 and when he returned last year to receive his M.B as the only graduate in uniform he received an ovation from the students After six months as casualty officer at Dundee Royal Infirmary, Dr Blair held assistantships at Blantyre and at Stockport, finally settling in practice with Dr. George Bridge at Preston At the outbreak of war, he joined the Royal Navy as a volunteer, and was posted as medical officer to a destroyer He was removed from her to be operated on for appendicitis three days before she was sunk Thereafter he became one of the residents in a naval hospital on the Forth until he joined the *Manistee* In 1933 he married Isabel Breen of Newport Fife They have two sons

Elliott & Fry

Blair spoke several languages easily and while still a boy attended the scout jamboree in Birkenhead as interpreter to the Belgian camp Gaelic was his pet study; and everything Highland had his devotion Standing well over six feet, he was a commanding figure in any company. He was an elder in the presbyterian church at Preston

Births, Marriages and Deaths

BIRTHS

BARNS —On June 28 in London, the wife of Mr H H F Barns, F R.C S —a son

ROUTLEY —On June 15, at Penang to Dr Barbara Routley (née Barnetson) wife of Dr Paul Routley—a son

SMYTH.—On June 27 at Sutton the wife of Captain Edward Smyth, R.A.M C —a son

MARRIAGES

CHAPMAN—TOPHAM —On June 14 at Bishop s Stortford Frederick John Shirley Chapman B M , to Gladys Emma Topham

COWPER—NEWITT —On June 21, at Woolacombe Claude Marriot Lovell Cowper, M.R C S , late of Leighton Buzzard to Irene Newitt.

MILNE—MAYOU —On June 28 at Boxmoor, R. Ian Milne M R C S , surgeon lieutenant R.N V R , to Jean Mayou Mayou

DEATHS

BROWN KELLY —On June 22 at Helensburgh Dumbartonshire, Adam Brown Kelly, M.D , D.Sc. LL D Glasg F R.F P S , aged 75

KING —On June 20, at Swindon Violet Maud Redman King M.B Leeds

LAING —On June 26, at Blairgowrie James Hill Williamson Laing M.A B Sc. St. And , M.B Edin

LLOYD ROBERTS —On June 24 at Maesincla, Caernarvon Griffith Lloyd Roberts M.D Edin.

McBRIDE —On June 25, at Dinton, Aylesbury, John Best McBride, L P C.P I L.M

MORGAN —On June 14 William Parry Morgan M.A. M B Camb B Sc Lond. formerly of 39 The Parade Cardiff

PIKE.—On June 26 at Lincoln Sir William Watson Pike K C M G , D.S O F R.C S I major-general late R.A.M C aged 81

STILL.—On June 28, at Salisbury Sir Frederic Still K C V O , M.D Camb LL D Edin., F R C.P

Appointments

BOYLE, E O , L A H Dubl D P H L.M M O H for Pudsey

DALLIWALL, KENNETH M.B Lond senior asst R.M.O at London Road Hospital Stoke-on Trent

DUTHIE E W , M.B Aberd examining factory surgeon for Cruden Aberdeenshire

ESSEX LOPRESTI PETER M R C S D A resident surgical registrar at Arlesey Emergency Hospital

FLAVELL, GEOFFREY F.R C S R S O at the Hospital for Consumption and Diseases of the Chest Brompton

MATHESON BERNARD, M.B Edin D.P M temp medical superintendent at South Okenden Colony, Essex.

MURRAY J R. M.D Lond D.P M resident medical superintendent at St George s Mental Hospital Morpeth

WILSON A E , M R.C S first asst M O at the Royal London Ophthalmic Hospital

Notes, Comments and Abstracts

SCANDINAVIAN ODYSSEY

IT was January, 1940, when our ambulance unit set off for Finland Movement was leisurely—we stopped in the North Sea to pick up some frozen survivors and did some ski-ing in Oslo while the ambulances were stuck in the ice I knew at least the theory of frostbite but soon heard awful stories of its insidious onset—how the ears went and the cheeks, and that then there came a strange emptiness between the thighs which ensured sterility A ladies' organisation had given us Balaclavas with flowing sides and by rearrangement these seemed to solve the problem, except for an epileptic patient whose custom it was to jump out of the window having first shed his garment This was a harmless pastime in summer, but when I saw him there were several feet of snow. I found, to my great advantage, that the major in charge of the Finnish hospital where I was to work was von Bonsdorff, of Helsinski University As the Red Cross was not recognised, the hospital had been carefully camouflaged by sticking small trees in the roof and hanging them around the walls, and with its covering of snow and surrounding woods it must have looked quite a plausible hillock from the air

There were usually air-raids in the mornings so little work was done then, and it was pleasant to spend the time ski-ing, racing back to the woods when the planes came too low The Finns were fighting under such difficulties that distinguishing the planes was no trouble —they were all Russian Electrocardiograms were taken in the afternoon even though we were so close to the front, and later I would take my patients over on a sleigh for X raying With sometimes eight barium meals to do in an evening I might have become a radiologist had the war lasted longer

Gastric cases predominated and when one saw—and ate—the pea soup, the rye bread and the substitute coffee this was understandable Combine this with mobile warfare which would not wait long enough to allow potatoes to be buried feet in the ground to prevent their being frozen and it seems strange that the whole army was not dyspeptic I did see one mild case of scurvy but ascorbic acid was included in the rations at the front and deficiency diseases were uncommon Typhus was never far from one's thoughts but I only saw one case in which it was even suspected Baths were taken at the front—in fact, the construction of baths seemed to be thought more important than the sleeping-quarters Perhaps one day we in this country will reach the cleanliness of the average Finn, if we cannot reach their civilisation in other respects Mild neuroses were fairly common, and it may be an index of the Finns' intelligence that they were nearly all anxiety states The one simple conversion hysteria which I remember had existed since the war of 1918 Hypnosis seemed easy when the patient did not understand a word of what was being said, but it failed to remove the stigma

To a foreigner the Finns seemed wonderfully enthusiastic in their carrying on of the war Of a dour nature, apart from the gay Karelians, they had simple war aims, for they were fighting for their lives and for land which had been lost and regained many times in past centuries The sudden peace with its cession of territory allowed them to indulge in depression—one of the few emotional directions in which they ever moved A nation in tears made one feel strangely embarrassed, and in the hushed corridors our heavy boots and uniforms seemed out of place

As the Finns were sending ambulances to Norway when the Germans invaded that country we felt that we must go too Every vehicle now had to be painted with large red crosses, for we were going to a civilised war Soon after entering Norway in broad daylight two planes proceeded to machine gun the convoy This altered our views and we got another shock when the British A D.M S gave us tea instead of whisky. We found the evacuation already completed, and came only to gaze on a ruined town and an empty bay There were motors in plenty and despite snow, mud and landslides we were back in Stockholm in a few days Some of our more warlike countrymen had to walk over the pass and a few of these suffered frostbite which I treated.

so, I hope, preventing their internment Besides trying to get away there was much of interest in Stockholm The new Karolinska Hospital is worthy of the city. Crafoord as a surgeon is well known but his hospitality is still more delightful

There were hundreds of people who wanted to return to Britain, and after being appointed M O to an official group I felt almost as if I were home The collapse of France made us dependent on our own effort The only way was by boat from Petsamo to America and belligerents were not allowed to travel So the next step was to obtain an Irish passport, but there were delays, and when the boat sailed it was captured by the Germans Again an Irish passport acted like magic, and even the Gestapo considered me harmless if sent back to Finland

In Lappland, while waiting for another boat, we would try to break some interest from eternity by rolling down rocks to sink deep in the pools below Soon we learnt more of this, a syndrome characterised by depression, craving for noise and excitement, and homicidal tendencies shown by letting boulders drop on people below, it is known as Lappland madness But in the end another boat did leave and I got back to England with the homicidal boulder still undropped J G

SIR JAMES LANCASTER AND THE CURE OF SCURVY

The East India Company, from the beginning of the seventeenth century, had a sound working knowledge of the prevention and cure of scurvy Many people assume that James Lind was the first medical authority to direct attention to the value of citrus fruits and that Captain James Cook was the first master-mariner to make use of them, but from 1601 the East India Company's ships carried a supply of oranges and lemons or of lemon juice for the protection of their crews [1] The published records of the Company leave no doubt that these were authorised items in the victualling of the fleet The man responsible for this was that incomparable ship-master Sir James Lancaster who sailed as Commander (or "Generall") of the first fleet sent by the Company to the East Indies in 1600 He was a tried seaman who had been employed some years before in the conduct of a privateering expedition to the East Indies An account of this is included in Hakluyt's "Principal Voyages of the English Nation," where he tells of a "Voyage with three tall ships to the East Indies in the yeere 1591 performed by M James Lancaster " On this occasion there is nothing to indicate that Lancaster was able to keep his crews free from scurvy nor that he recognised the superior value of oranges and lemons as a remedy Yet when we read the account—in "Purchas his Pilgrimes"—of "the first Voyage set forth by the East India Company in 1600" it is evident that Lancaster had by then a sound grasp of the prevention and cure of scurvy The men of his ship "stood in better health than the men of the other ships," and the reason was that "he brought to sea with him certaine bottles of the juices of limons, which he gave to each one as long as it would last, three spoonfuls every morning" There are several other references in this account to the superiority of oranges and lemons "which were precious for our diseased men to purge their bodies of the scurvy" The editors of the "First Letterbook of the East India Company, 1616-1619" in a footnote to an entry of lemon water among the victuals say "We may trace in this item the hand of Sir James Lancaster who was one of the first to use the juice of lemons as an antidote to scurvy" The measure was not formally adopted by the Admiralty until 1795—nearly two centuries later After this entry there are letters of complaint in which the Company's captains brought to the directors' notice that the ships' stores did not include oranges and lemons or lemon juice—a dereliction which they would not condone Woodall, surgeon-general to the East India Company, about the time of Lancaster, gave lemon-juice a prominent place in the cure of scurvy in his book, "The Surgeon's Mate," published in 1628, so the remedy was not kept secret by the East India Company Yet one might suppose that the Navy had never heard of it until Captain Cook's Voyage in 1769, after which "limey" became the term for a British sailor The lime-juice ration which earned this title was not at first made from limes (which have poor ascorbic properties) but from the juice of Mediterranean lemons In the middle of the nineteenth century, partly for political reasons, the juice of West Indian limes was substituted, and by 1870 very little, if any, lemon juice was issued officially The inferiority of lime juice as compared with lemon juice has been repeatedly demonstrated on Arctic expeditions The whole early history is accurately and clearly set out by George Budd in his article on scurvy in "Tweedie's System of Practical Medicine"

Medical News

University of Oxford

The Weldon prize for 1941 has been awarded to Dr Julia Bell, Galton research fellow of University College, London, and a member of the scientific staff of the Medical Research Council

Prof T B Davie has been appointed an examiner in special and clinical pathology in the B M examinations until 1942, and Dr A H T Robb Smith until 1943

University of Glasgow

On June 27 the degree of M D was conferred on A L McAdam, J G Scott, and (in absentia) on W I Walker

The Harry Stewart Hutchison prize was awarded to Dr Theodore Crawford, and Dr Esther Hendry

University of Bristol

At recent examinations the following were successful -

FINAL EXAMINATION FOR M B, CH B

G S Andrews and Marie L Bartlett (first class honours), Cecil M Drillien and J C Valentine (second class honours), R C Blackney, N J Brown, J D Cardale, G T Cribb, J H P Davies Sage, Mary L Hunt, D S Maunsell, H R Newman, Christine V Rendell, F B Richards, M O Skelton, J H Wilkins

Group II (completing the examination) —J B Tucker

Order of St John of Jerusalem

The King has sanctioned the following promotions in an appointments to the Venerable Order of the Hospital of St John of Jerusalem —

As Knight —Lord Horder, M D, Major General Sir Eugene Fisc M D, Lieut Colonel Ian Fraser, F R C S, Samuel McCormac, M

As Commander —Captain Richard Williams, M R C S, Maj Stanley Copley, F R C S, G B Peat, M D, Colonel W W Whit M D, Lieut General Sir Gordon Jolly, I M S, Major A T Smit M D

As Officer —J E Dovey, M B, Captain G W C Bissett, M D J A Corrigan, M D, H A Creighton M D, A G Morris, M D E W Stewart, M D, Lieut Colonel J W Tice, M D Lieut Colon F A Barker, I M S retd, John Ferguson, M D, H B Pierce, M B A M Robertson, L R C P E, John Wells, M R C S, Lieut Colon W S C Copeman, F R C P

Shaftesbury Military Hospital Medical Society

At a meeting of this society on July 8, at 3 P M, the speake will be Dr Paul Beeson, chief physician to the America Hospital which is being established in this country

Medical Personnel (Priority) Committee

Dr G C Anderson, as secretary of the Central Medica War Committee, has been invited to attend the meetings c the Medical Personnel (Priority) Committee in an advisor capacity The composition of this committee, of whic Mr Geoffrey Shakespeare, M P, is chairman, was set out i our parliamentary columns last week

The Derry Gardens in Kensington High Street will be ope for the benefit of St Bartholomew's Hospital from Monday July 7 to Saturday, July 12 from 9 30 A M to 6 P M except o Saturday when they close at 1 P M

The George medal has been awarded to Dr Hannah Bill and Dr Bernard Doyle of Stepney and to Dr Aliso McNairn of Plymouth

CORRIGENDUM —Two corrections should be made i Dr Hodgson's paper of last week On page 812, column 1 12 lines from the bottom, read pil colocynth co gr 5 and the first acknowledgement on page 813 should b to Dr Elsie Burns

SOMATIC FACTORS CONDITIONING AIR-RAID REACTIONS*

H. CRICHTON-MILLER, M.D. Edin., F.R.C.P.
PHYSICIAN TO THE TAVISTOCK CLINIC AND TO BOWDEN HOUSE, HARROW

MUCH has been said and written about the psychological reactions of civilians to air-bombardment, less about the physical effects that may ensue in the absence of overt trauma, and still less about the relationship of physical and emotional factors. Official policy applauds the morale of the civil population, and claims that functional disabilities attributable to the blitzkrieg are negligible. Moral courage and self-respect can entirely eliminate self-pity and malingering, so that if we think of all functional disabilities as due to one of these causes, or to a combination of the two, we must think of functional disability as evidence of low morale. I suggest that many of the functional results of air-bombardment on the unwounded have no relation whatsoever to any moral quality.

BLAST-CONCUSSION

When high explosives were first used on the battlefield cases began to appear of soldiers who had not been wounded and who did not appear to have experienced any impact concussion, who yet presented the general picture of post-concussion cases. To this condition was given the name of shell-shock. Soon the symptom began to be associated with anxiety, hysteria and malingering. From 1914 to 1918, and afterwards, the differential diagnosis of these cases was erratic and confused. It was inevitable that the public should readily take to the word shell-shock; it covered a multitude of disabilities and some sins too. The Government became somewhat embarrassed. After the war a commission was appointed to investigate the problem, and reached a conclusion which may not unfairly be formulated thus: "We cannot deny that there is such a condition as true shell-shock, but it has been so much abused that we must never again admit its existence." Then came twenty years of peace and pensions. When Hitler's war seemed imminent more committees met, and it was decided that whatever might happen in this war there was to be no shell-shock. The naïf conviction that a symptom can be eliminated by refraining from allowing it a name had its inevitable result. The symptom appeared, a designation had to be found for it, and so the clinicians—as opposed to the ministerial authorities—described it as blast-concussion. It is to be hoped that this name will not be exploited in the way in which shell-shock was exploited; but if it should be the fault will lie not in the name but in the situation. Every mother of a young schizophrenic remembers an occasion when, as an infant, her son fell out of his perambulator and landed on his head. This is very natural. A fall from a pram is, to the popular mind, a highly respectable ætiology; hereditary and other intangible explanations are unpleasant or actually compromising. Shell-shock was more respectable than malingering, so will blast-concussion always be more acceptable than hysteria. These subjective distortions will persist as long as a semi-educated public can escape from a diagnosis that it fears or dislikes. Nor will these distortions be effectively eliminated by a highly educated government department vetoing the use of any particular nomenclature.

What, then, is this blast-concussion? Since air-bombardment began in this country the public has had numerous opportunities of observing the remarkable effects of blast. We have seen plate-glass windows shattered and the fragments hurled against the opposite wall, while the fragments of an adjoining window were caught by the vacuum and deposited in the street. It is reasonable to suppose that similar blast effects, of compression and suction, acting on an elastic abdominal wall should displace the fluids of the body with extreme violence to or from that part of the human anatomy which alone is immune from external pressure—the brain. When we think of blast powerful enough to lift a man many feet into the air, we realise dimly the immeasurable strain imposed on the infinitely delicate structure of the central nervous system with its network of ill-supported cells and motile synapses. Perhaps the nearest experience that many of us may have had to blast-concussion is the flat dive—the "belly-flopper" of our schooldays—an experience which can be associated with headache of such intensity as to convince the subject that some mechanism such as I have described is operative. This is further confirmed by the fact that in fatal cases punctate hæmorrhages may be found post mortem not only in the meninges but even throughout the brain substance.

The treatment for blast-concussion is the same as for impact concussion: absolute rest and withdrawal of all stimulation. It is therefore clear that in all cases of functional breakdown after an air-raid this factor of blast-concussion should be considered. If it is present it must be treated. Unfortunately, it is by no means easy to determine its presence except in well-marked cases or where third-party evidence is available. Furthermore, it is characteristic of all except the severest concussion that the patient is restless and even compulsively active before it is expedient for him to move. Hence the doctor who encourages his concussion case to discharge himself and go home may be doing good work from the point of view of official statistics, but he is doing very bad work from the point of view of sound treatment.

Enough has been said to show fairly clearly that blast-concussion is a not unnatural consequence of exposure to a nearby explosion, that it has no intrinsic connexion with psychology, and that it bears no relation to morale, courage, discipline or any other ethical virtue. I have said "intrinsic connexion" with psychology because extrinsic association is very common. For instance, a man may be suffering from acute anxiety when the blast knocks him out; or alternatively it may affect him without any warning so that he has literally "no time to be frightened." The physiological state will be different in either case, and it is reasonable to suppose that the ultimate clinical picture is influenced thereby. Similarly, a hysterical woman can exploit the effects of blast-concussion in the same unconscious or semi-volitional way in which she would exploit any other disability. Thus we reach the first step in somatic conditioning of air-raid reactions: the combination of the organic factor of concussion with the emotional factor of fear. In all functional disabilities we are liable to find this phenomenon of synergy, and for this reason the physician who deals with functional disorders must command an absolutely open mind. If he approaches the case with bias in favour of a psychological ætiology, or with bias towards an organic causation, or—worst of all—with the conviction that all unwounded patients are malingerers, then he is not likely to find anything but confirmation of his own preconceptions.

In a large number of cases, however, the man who has been exposed to blast has also been wounded; that is the great safeguard. The wound is probably severe enough to ensure the rest which is essential for the cure of the concussion, and to disarm the scepticism and lack of sympathy liable to be manifested both professionally and domestically. Moreover, the subjective effect must not be ignored: there is an irrational feeling of loss of prestige, a lowering of the ego-ideal, a hurt to one's narcissism, in being disabled without obvious trauma. For all these reasons we may expect the worst effects of blast-concussion to show themselves in the unwounded.

PHYSIOLOGICAL FACTORS INFLUENCING RECOVERY

All fluctuations in vital efficiency modify in some measure both the intensity of instinctive and emotional reactions and the effectiveness of cortical control. An exhausted man reacts to the fear of death or to acute pain in a manner and measure different from his normal. Exhaustion within physiological limits is associated with a lowering of the blood-sugar to fasting level or below it; we may take other aspects under the heading of pathological exhaustion. It is for this reason that all

---

* A paper read before the British Psychological Society on April 19, 1941

A R P personnel are urged to give sugar in large quantities It is certainly the best treatment in exhausted cases, but its indiscriminate administration is open to serious criticism In assessing exhaustion we must always bear in mind the possibility of complicating factors that militate against recuperation such as anæmia Apart from such factors we should expect the ordinary case of exhaustion to recover if he is given fluid, nourishment, sugar and the opportunity of ten hours sleep

Age is important, children stand up to bombing remarkably well What they do not resist is the contagion of panic and hysteria on the part of their elders It is easy to understand why this should be so The child's conceptual life has not yet been infiltrated by narcissistic susceptibility to a remote fear of death, but when it sees adults in a state of panic it succumbs to the idea that there must be something to fear in the loud noises, or even in the wail of the sirens Some old people react well, some badly

I recall two patients who came into hospital about the same time The one was a railway porter and the other a retired civil servant They were both in the late sixties The porter had experienced a fairly severe blast-concussion, the other was suffering solely from emotional effects The porter was anxious to recover and get back to his home, his wife and his grandchildren The civil servant had a history of a most imperfect, if not actually abnormal, sex-life which included marriage to a widow with a family and no children of his own There was plenty of evidence that the generative life of the porter had been full and normal as against the inadequacy and dissatisfaction of the civil servant's The porter made an excellent and rapid recovery the civil servant proved to be a senile narcissan of the most refractory type The two men belonged to recognisable groups, some of us will contrast them on the plane of their emotional histories, others will think of them in terms of endocrine normality and endocrine deficiency All that matters is that we should agree in attributing the recovery of the porter to normality of mind and body rather than to any ethical superiority, and in this normality I should include his parental status, for is not parenthood nature's incomparable solvent of narcissism? As far as arteriosclerosis went, the facts were in favour of the civil servant and not of the porter Nevertheless, circulatory disturbances of a degenerative kind are undoubtedly responsible for some of the worst cases among the aged

Other aspects of the generative life demand consideration The menstrual cycle is important, if for no other reason, because within that cycle there is always a point at which exhibitionism and therefore hysteria is at its maximum, and another at which these tendencies are at their minimum Similarly, the anxiety that can be associated with the menstrual cycle—based on fear of, or desire for, conception—may well furnish a conditioning factor in behaviour The climacteric is an epoch at which we never expect rational control of the emotional life to be at its best It is a period of transition in the endocrine balance, when the equilibrium between androgen and œstrogen hormones is being modified At the same time, it is a period of finality in the course of the generative emotions Reaction to bombardment on the part of the menopausal woman is likely to reflect those factors of instability attributable to these two causes Thus the subovarian childless woman may react relatively well, the hyperovarian woman with no children rarely, if ever, makes a good showing, the woman who has had a full married life and born a number of children may behave as normally as at any other time of her life, and the grandmothers of the community have, in general, reacted with impressive serenity

Another condition of theoretical interest is lactation I regret that no cases of this group have come under my observation Lactation is the epoch in which a woman's narcissism is most completely transformed by her relation of indispensability to her helpless infant, and by the instinctive impulse to give, apart from any reciprocation In fact, this is parenthood in excelsis, and the views already expressed should apply Here is an analysis of 47 cases of anxiety following bombardment treated as inpatients at a hospital in the London area

There may be little significance in any of the rest of the figures in the table, but the last line must surely command our interest It means that of 47 people o an average age of 38 4 years only 6 were leading married lives that could be called normal, 21 were unmarried, several were widowed, some were separated from thei spouses and others observing sexual abstinence or practising coitus interruptus

—	Males	Females	Total
Cases	29	18	4
Average age	42 4	31 9	38 4
Married	20	6	26
Av no of children (married patients only)	2 3	1 1	—
Married cases leading normal marital life	5	1	6

PATHOLOGICAL FACTORS

Apart from physiological conditions liable to exer their influence on conduct, some pathological condition are likely to condition behaviour in air-raids Among them is exhaustion of a degree that can no longer b described as physiological, and which demands treatmen on a different scale As a useful, if rough, index we ma take note of the interference with sleep A man "to tired to sleep" may be regarded as pathologicall exhausted We may consider such a state as being base in the main on the following factors blood-sugar at c below fasting level, low blood-pressure (perhaps mo accurately, lowered pulse-pressure), adrenal and glyc gen exhaustion, histamine poisoning What interes us here is the effect of these factors on behaviour T understand this we must at the same time consider th question of anoxæmia Theoretically, any physic factor which results in a reduction of oxygen supply the cells of the central nervous system inevitably caus a modification of behaviour Presumably this involv two factors general lowering of nerve potential, a differential lowering of cortical, as opposed to hyp thalamic, potential The former results in despondenc apathy, inertia and even mild confusion, while the latt results in some form or another of uncontroll behaviour, whether that be the restrained anxiety of th introvert or the unrestrained hysteria of the extraver This presumption, or some similar theory, is required help us to explain a case like the following

A man with a definite anæmia soon becomes exhausted his task of fire fighting, he is not terrified, he is weary a despondent, he finds rest and security in a shelter, he given fluid, nourishment and sugar, he becomes anxiou his apathy changes, he starts to tremble, he breaks out cold sweats, he groans quietly and later becomes restle pacing up and down the shelter We may ask ourselves wh has this man suffering from obvious exhaustion been tran formed into a typical anxiety case? Why did anxiety bes him only when he was in a place of safety and not when was exposed to danger? It is permissible to suppose that t exhausted man was apathetic and despondent by reason o lowered nerve potential that affected his entire central nervo system, and that when he was refreshed by rest and nouris ment the potential of his emotional centres was raised, witho a corresponding rise in cortical potential this latter fa might reasonably be attributed to the oxygen deficien resulting from his anæmia

THE PENALTY OF SELF-CONTROL

We can be clear at least about the primary instincti and biological sequence fear → adrenal response mobilisation of glucose → increased muscular tone pl enhanced aggressivity → fight or flight When troo are about to attack it is desirable that aggressivity shou be at its maximum When civilians are exposed to a bombardment fortitude, endurance and self-control a called for In the former case the instinctive purpose aggression is utilised, in the latter there is no oppo tunity for aggression and the alternative purpose of flig must be controlled In the first case we are working o an instinctive, in the second on a civilised, pattern conduct Hence it follows that in the presence of oppo tunities for retaliation a great deal depends on th emotional drive, in the absence of any such opportunit it is cortical control that is the deciding factor i behaviour

This situation can be clarified by reference to animal haviour The concomitants of fear in animals are miliar to all The rabbit's fear of death produces a ate of hyperglycæmia which finds expression in its ight from the predatory stoat, and thereby serves the urpose of self-preservation When the cat turns on e pursuing terrier with arched back and bristling fur s fear of suffering is transformed into an aggressive eaction When the lamb feels the pangs of hunger it leats and thereby appeals to the ewe to terminate its eelings of frustration When the duckling is separated rom its convoy it signals audibly its fear of isolation and nsures speedy protection Such are the simple reactions o instinctive fear which are shared with the animals by hildren and primitive people But when the child's education begins and when man becomes culturally controlled a new element enters in The infant's cry for the mother's breast was tolerated, but Tommy is told that he must not yell or shout for his tea—he must control himself till the bell rings The boy is called on to endure frustration and to refrain from any appeal for its termination The biological intolerance of instinctual frustration must be superseded by the cultural demand for controlled behaviour The maiden of a primitive tribe, beset by the pangs of sex-hunger, makes no secret of her feelings What we call modesty in civilised society consists in refraining from such conduct as can be interpreted as a solicitation of the potential mate—that is in refraining from any direct appeal for instinctual satisfaction Thus in a civilised community, fear of frustration—as of death and suffering—may be endured in a latent or overt way If it is latent it constitutes anxiety , if it is expressed we call it hysteria The important point to realise is that, in so far as all hysterical dramatisation partakes of the nature of an appeal for protection or satisfaction, so it drains off anxiety which has been accumulated by interference with the “ fight or flight ” mechanism

If we apply all this to air-raid reactions it is clear that in any shelter under bombardment we may encounter any of the following forms of behaviour ·

1 The crude manifestation of *pugnacity* in an aggressive type of individual who picks a quarrel with the shelter marshal or the police on wholly inadequate grounds Such people should, of course, be outside any shelter , they should be armed with hose and axe, or better still manning an A.A. gun

2 The equally inappropriate *flight reaction* I have known a highly intelligent and educated woman who rushed out of a shelter against advice to her own grave peril , and an elderly London taxi-driver who during a bombardment refused to go into a shelter and simply drove into the country till his petrol was exhausted. These two types represent the complete breakdown of cortical control the pure pattern of instinctive reaction to fear , their incidence serves to remind us how thin may be the veneer of civilisation

3 The *anxiety case,* silently trembling and sweating , perhaps pacing up and down, alert, taut and incapable of relaxing himself , hardly controlling himself as each gun fires or each bomb explodes

4 The *hysteric,* who by a hundred different forms of behaviour proclaims her need for protection, and, perhaps more, her craving for compassion, admiration or interest Her anxiety is completely socialised, and is therefore relieved by the knowledge that, in so far as security can be ensured, she will be the last to suffer

5 The case of *anxiety-hysteria,* maintaining only limited control of conduct, unable to refrain from a partial publicity campaign, and yet capable of enduring a measure of unrelieved fear In war-time, as in peace, this last mixed form is the one we encounter most frequently

In addition to these five groups of fear-determined reaction there are always the cases of pure blast-concussion which, as has already been pointed out, have no psychogenesis whatsoever

Anxiety, then, is the price man pays for a culture that demands inhibition of fear and hate reactions Anxiety is unrelieved fear, or, more fully, anxiety is the fear of death, suffering or frustration unrelieved by aggressive action, by flight to security, by instinctual satisfaction or by an appeal for protection or satisfaction We thus see the relationship between fear, opportunity for retaliation and attainment of security These factors represent the triangle of anxiety—anxiety worked off by dynamic action Fear possibility of human help, the dramatised appeal represent the triangle of hysteria—anxiety replaced by the dramatic appeal

ENDOCRINE AND SEPTIC FACTORS

All these cases may be considered from the point of view of instinctive emotion applied, consciously or unconsciously to an end in which cortical control more or less enters in Any somatic factors liable to influence either emotional pressure or cortical direction therefore deserve consideration. Two groups of causative factors are of special significance . endocrine and septic. Something has already been said of the endocrine conditioning of behaviour , but in contemplating the rôle of the adrenals in interpreting emotions of fear and hate we can never ignore the factor of the gonads As the adrenals of the male afford the necessary aggressivity for the sexual function so the testes contribute desire and potential fertility The eastern potentate of legend if not of reality, sated with years of satisfaction in his harem, becomes obese and loses all aggressiveness (or at least courageous aggressiveness) No doubt the endocrinologist would tell us that the man is the subject of pituitary degeneration Be that as it may, the practical import, as far as his conduct goes, consists in reduced adrenal resources On the other hand, in the woman of 50 who has mothered a sizeable family and led a full marital life aggressiveness has presumably increased as gonad function has begun to wane , and thereby she achieves a state of personal independence perhaps greater than she has reached in any previous epoch

But endocrine speculations, however intriguing, must be justified in practical therapy There is accumulating evidence that in desoxycorticosterone we have a synthetic hormone which has a direct influence on aggressiveness, and therefore, in certain cases, on potence in the male At the same time, the estimation of androgen and œstrogen hormones excreted gives us a fresh approach to the whole problem of endocrine function in relation to the conduct of the female

Turning to the question of toxæmia the problem is in the main one of anæmia, consequent anoxæmia and resultant lowering of cortical control No-one with an open eye and mind can fail to realise the all but universal incidence of the toxic factor in functional disability The psychotherapist who conducts a lengthy analysis without any examination of the patient's metabolic status will collect interesting information about œdipus reactions and breast trauma, but he will never know that his patient is suffering from a secondary anæmia and so will never doubt that the patient's ultimate improvement was exclusively due to successful analysis The fact that towards the end of the analysis the dentist extracted a molar with a large apical abscess even if known to him, will not shake his interpretation of therapeutic results

The following case is an example of synergic ætiology in relation to air-bombardment

A railway guard aged 48, married, with 2 children Had his house completely demolished by a bomb just after he and his family had taken cover in a public shelter A powerfully built man tending to obesity When seen was a mass of anxiety, trembling, sighing, restless and reluctant at first to remain in hospital He was the son of a dock labourer, the 5th child of 15 The father was consistently drunk and incredibly cruel “ E took a great 'obby in knockin' mother about ” He beat all his children fiercely and without any relation to justice The children were always ill-clothed and generally hungry At 16 the patient ran away to sea and at 18 enlisted At 22 he was a sergeant in a line regiment in France During the whole of the war he served in France He was never wounded nor had any trace of functional disability After the war he joined the railway At 39 he was in a collision, sustained a fractured arm and was three months off work, being badly troubled by his “ nerves ” At 40 another railway collision, this time a fractured leg and again trouble with his nerves A session of narco analysis with Pentothal produced much abreaction chiefly on two subjects his father beating him, and his wife calling him a coward for his behaviour in the shelter and for refusing to come out after the all-clear “ Why didn't they do me in in the last war ? What a coward I'm sorry, girl, I can t 'elp it , let me stop 'ere ·I m not going out . . All right, call me a coward . ” On the physical side the only abnormality of importance was dental sepsis which necessitated total extractions

This man was suffering from acute anxiety superimposed on a progressive toxic neurasthenia He had been in the line during most of the great war and apparently conducted himself with credit Our problem is to analyse the causative factors which produced so great a transformation The first point that strikes the medical psychologist is the factor of retaliation Owing to his upbringing at the hands of a savage father he reached manhood with extreme repressions of fear and hate for the overmastering father-figure In France during the great war he was rarely without opportunities to retaliate , his aggression could be worked off, and his emotional balance was thus preserved In both his collisions, and even more strikingly in the air-raid, he was helpless unable to retaliate and obliged to control his own aggression The pressure of the resultant anxiety was such that he developed some hysterical features as an outlet But in the air-raid the situation was complicated by his wife's scorn and impatience ; that would naturally divert aggression in her direction, and this tendency would render the task of passive endurance still more difficult But there were other factors to be taken into account In the great war he was leading a bachelor life (and indeed up to the time war broke out he was in strict training both for boxing and long-distance swimming) In the period covered by his two collisions and the air-raid he had been leading a marital life that could in no way be described as normal, and which involved a very considerable sense of guilt Finally the factor of sepsis was severe Indeed the teeth were so septic that the extractions had to be spread over a period of days It is easy to believe that this toxæmia dated back to the time of the first collision I submit then that the total clinical picture resulted from a definite toxæmia, from grossly traumatic experiences in childhood, and from a marital life charged with fear and guilt , it seems to me that the elimination of any one of these factors would appreciably have modified the character of the man's breakdown

SUMMARY

The blast effects of compression and suction acting on an elastic abdominal wall probably cause fluid to be violently displaced inside the skull This no doubt damages the function of the delicate and ill-supported cells of the brain Thus pure blast concussion has no psychogenesis

The symptoms developing will depend, however, not only on this mechanical factor, but on the psychological state of the patient when the blast knocks him out Thus the organic factor of concussion may be combined with the emotional factor of fear, just as each may occur independently

If the patient has also been wounded he will probably get rest enough to cure the effects of blast concussion If not, he may feel loss of prestige in being disabled without obvious trauma , thus the worst effects of blast concussion are seen in the unwounded

Fatigue, age, the biological epochs, arterial degeneration and an abnormal sexual and emotional life are factors influencing recovery Fatigue is associated with a fall in blood-sugar , indiscriminate sugar administration may convert fatigue apathy into anxiety

Pathological factors affecting recovery from blast-concussion include extreme exhaustion , anæmia and consequent anoxæmia , frustration—with resultant anxiety—of instinctive impulses towards aggression, flight, or an appeal for protection

Endocrine factors are still obscure, but there is evidence that desoxycorticosterone has a direct action in increasing aggressiveness

Toxic absorption from a septic focus can also influence recovery

DI-IODOTYROSINE IN TREATMENT O GRAVES'S DISEASE

S H WASS, M S Lond , F R C S
SURGICAL REGISTRAR TO GUY'S HOSPITAL

THE use of di-iodotyrosine in the treatment of Grave disease has not achieved much prominence in th country A list of references supplied by the man facturers contained, apart from the work of Haringt and Randall (1929), only one British reference to its u (Kean 1937) On the Continent, however, much expe mental and clinical work has been done with the drug

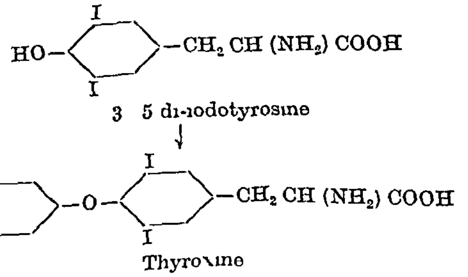
In view of the advantages claimed for this substan over iodine it was decided that a trial of its possibilit should be made Unfortunately it has been impossil to carry out any comprehensive investigation owing the relative lack of clinical material The large seri of cases available in the important American clini cannot be equalled in this country, and without reaso able numbers of cases and controls no conclusions ca be drawn from an investigation of this type. This wo therefore, is intended merely to stimulate further wo on the subject

The advantages claimed for di-iodotyrosine ov iodine in the treatment of Graves's disease are that remission of the disease is produced more rapidl satisfactory remissions are produced even after p longed administration of iodine , treatment can stopped and resumed at a later date, further remissio still being obtained , treatment can be continued o longer periods than with iodine without produci undesirable effects , and no secondary effects (iodis are observable as with inorganic iodine

CHEMISTRY

Di-iodotyrosine (*dl* 3 5-di-iodotyrosine) was isola by Harington and Randall (1929) from the acid-solu fraction after barium hydroxide hydrolysis of desiccat thyroid gland This acid-soluble fraction, yieldi di-iodotyrosine, was not physiologically active, while acid-insoluble fraction from which thyroxine was isolat showed active physiological properties These work claim that the whole of the acid-soluble iodine in thyroid gland is present as di-iodotyrosine and whole of the acid-insoluble iodine as thyroxine T total iodine content of the gland is roughly equa divided between these two fractions, but variatio occur which account for the lack of parallelism betwe the total iodine content and the physiological activi of the dried gland Thus in varying states of activi of the gland we find varying proportions of the tot iodine present as thyroxine and as di-iodotyrosine

Di-iodotyrosine is the immediate precursor of thyroxi an oxidative coupling taking place with the loss of o side-chain (Harington and Barger 1927) thus



3 5 di-iodotyrosine

Thyroxine

It is probable that the thyroxine formed in the glan is stored in the colloid in combination with globuli (thyroglobulin) which is broken down to thyroxine whe the latter is required

ACTION OF IODINE IN GRAVES'S DISEASE

A course of iodine in primary Graves's disease as a rul produces a remarkable remission This effect is maxima after 7–14 days when the drug is being administered fo the first time Second and third remissions wit peated courses of iodine are much less common and er prolonged exhibition of the drug it either ceases to ve any effect or produces a definite deterioration in e patient's condition In secondary Graves's disease odular toxic goitre and the so-called toxic-adenoma pes) the good effect of iodine is always less obvious, nd is usually absent altogether, sometimes iodine even ppears to affect the patient's condition adversely from he start

This striking difference in the action of iodine in the rimary and secondary types of Graves's disease was reviously interpreted as implying that the thyroid gland roduced different secretions in the two types of the isease It was argued that secondary Graves's disease was an example of simple hyperthyroidism and that the giving of iodine could only result in a further increase in the production of thyroxine Primary Graves's disease, however was considered as an example of dysthyroidism, the gland supposedly producing a "toxic" secretion, in such cases iodine was credited with the power of restoring this secretion to normal and thus producing an improvement in the patient's clinical condition No explanation was forthcoming to account either for the failure of continued improvement with continued iodine administration or for the failure of iodine to produce a remission when given for a second or third time There seems to be little or no evidence to support this hypothesis, and in the light of modern work both types of Graves's disease must be considered to be examples of simple hypersecretion of the thyroid gland

Many other hypotheses have been formulated to account for the action of iodine in Graves's disease but none has proved satisfactory. Slesinger (personal communication), however, has put forward an explanation which accounts for most of the established facts He argues that the exhibition of iodine does allow of increased production of thyroxine, but, whereas this was previously swept out into the circulation as fast as it was produced (as evidenced by the empty alveoli seen in microscopical sections of the gland), it is now formed in such quantity that supply exceeds demand Combination with globulin thus occurs and colloid storage in the alveoli now becomes possible With this storage of colloid the tension within the gland capsule increases considerably. leading to compression of the absorbing capillaries and lymphatics The vicious circle is now broken, the rate of absorption of thyroxine is lower the blood thyroxine falls and there is a parallel improvement in the clinical condition Thus the ultimate factor accounting for the beneficial effect of iodine is purely mechanical

There is ample evidence in support of this hypothesis The histological appearance of the thyroid gland after iodine administration shows the extent to which colloid storage takes place. The characteristic hardness of the iodinised gland on clinical examination is a measure of the increased tension within the gland capsule The disappearance of the systolic thrill and bruit over the gland signifies a decreased blood-supply and a lowered physiological activity. There must obviously be a limit to the degree of tension attainable within the gland and when this limit is reached no further improvement can be expected from continued administration of iodine, its work has been done in breaking the vicious circle In cases of secondary Graves's disease the thyroid gland is nodular, and the characteristic histological appearance is one of fibrosis with scattered areas of hyperactive thyroid tissue alternating with large colloid nodules In such cases iodine cannot be expected to exhibit an "elective affinity" for the hyperactive areas of tissue Moreover, since a large part of the gland is already in the colloid state, any increase in tension within the gland must be small compared with the effect produced in the large diffusely hyperactive gland of primary Graves's disease This is shown by the absence of clinical hardening of the gland and by the failure of iodine to produce a remission in this type of case

It may justifiably be stated that the careful use of iodine in cases of primary Graves's disease, especially as an immediate preoperative measure, has been the major factor responsible for the great fall in the mortality of the disease. Its use has become standardised and is on the whole exceedingly satisfactory. Occasional failures occur, however, and there is still room for improvements As the immediate precursor of thyroxine, di-iodotyrosine might be expected to allow of a more rapid formation and storage of colloid in the hyperactive gland and therefore, on Slesinger's hypothesis, of a more rapid improvement in the clinical condition

EFFECTS OF DI-IODOTYROSINE

Di-iodotyrosine "Roche" was the preparation used in this study It is made up in tablets each containing gr 1½ The recommended dose is ½–3 tablets daily, but in most of the cases under consideration the optimum dosage was found to be 2 tablets daily

A solution of di-iodotyrosine is also available for intravenous use, each ampoule contains 1 c cm of a 5% solution which is equivalent to half a tablet It was intended that these ampoules should be used in postoperative thyrotoxic crises, but no such crisis occurred during the period of study of these cases Moreover, the routine postoperative treatment of thyroidectomy patients with rectal iodine has proved so satisfactory that no opportunity arose for experimenting with intravenous di iodotyrosine In this series of cases, therefore, I have studied only the effects of oral administration of di-iodotyrosine, principally as a method of preoperative preparation

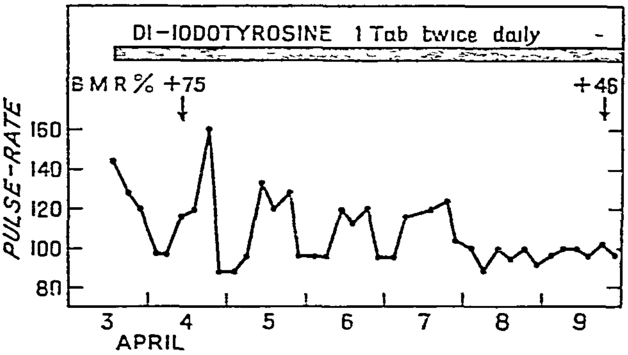


FIG 1—Four-hourly pulse chart of man, aged 33, with primary Graves's disease Remission obtained with di iodotyrosine

As a substitute for iodine—With the limited number of cases available it was realised that comparable control cases treated with iodine and with rest alone were unattainable. I therefore decided to put the new preparation to the strictest test available by confining its use to the most severe cases The criterion taken was a basal metabolic rate of +65% or over, all cases in this group were treated preoperatively with di-iodotyrosine, the remainder with iodine alone The results in this group confirmed the experimental (Abelin 1931) and clinical (Schurmeyer and Wissmann 1932) evidence that di-iodotyrosine produces a fall in the basal metabolic rate Of 10 cases investigated a satisfactory remission of the disease was obtained in 9, 6 of the 10 were subjected to subtotal thyroidectomy in one stage, and in 3 a two-stage excision was deemed advisable In the tenth case, in which no improvement in the patient's condition was obtained with di-iodotyrosine, preliminary ligation of the superior thyroid arteries was followed by successful two-stage subtotal thyroidectomy. There were no deaths in this group In the 9 cases showing remissions after exhibition of di-iodotyrosine the average fall in the basal metabolic rate was from +84% to +50% in 8 days The pulse charts in these cases showed a fall in rate together with disappearance of the hourly variation in rate which is characteristic of thyrotoxicosis A typical pulse chart (fig 1) does not differ in any way from that of a typical remission produced by iodine, and the time taken to produce the improvement was approximately the same as that taken by iodine The average fall in basal metabolic rate during this period was also similar to that obtained by the use of iodine in comparable severe cases. Only one opportunity arose for trying the effect of di-iodotyrosine in a case where iodine had failed to produce a remission The fact that such failures are rare speaks well for the value of iodine In this case the patient's pulse-rate failed to settle and the basal metabolic rate fell only 5% (+ 65% to + 60%) after a fortnight's treatment with Lugol's iodine, ℳ 10 t d s A further ten days' treatment with di-iodotyrosine (2 tablets daily) also failed to produce any improvement or stabilisation of the pulse-rate Preliminary arterial ligation in this case was followed by successful subtotal thyroidectomy in two stages

Iodine is almost universally successful in producing a satisfactory preoperative state in Graves's disease, and although di-iodotyrosine produced similar effects in the more severe cases of this series its results showed no definite advantage, either in degree or rapidity of action, over those obtainable with iodine alone There seems, therefore, to be no justification for recommending the routine use of the more expensive preparation In the rare cases where iodine fails to improve the patient's condition further work is needed to determine whether or not di-iodotyrosine will succeed

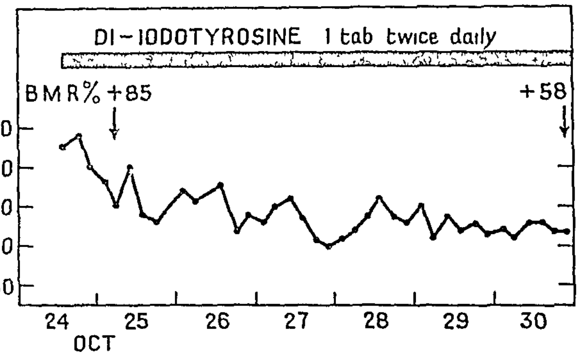

FIG 2—Four hourly pulse chart of woman, aged 42, with primary Graves's disease previously treated with Lugol's iodine continuously for six months Remission obtained with di iodotyrosine

After prolonged administration of iodine—One of the dangers of the beneficial effects of iodine in Graves's disease is that its use may be misdirected Since the maximal effect of iodine can be produced once only, many writers have advocated that it should not be used in the routine medical treatment of Graves's disease but reserved as a preoperative measure This is undoubtedly the correct attitude, for if the patient should ultimately come to operation the maximal effect of iodine would not be available at that stage and consequently the operative risk would be greater In spite of this teaching, however, it is only too common to have patients with Graves's disease referred to the consultant after the practitioner has been prescribing Lugol's iodine over a considerable period When the case is one for surgery this state of affairs gives rise to considerable misgiving The usual course taken is to omit the iodine for some time and to give it again for about ten days prior to operation, in the hope of producing some improvement in the degree of hyperthyroidism and of making the patient fit for surgery This is not entirely satisfactory for an adequate remission does not always occur A trial was therefore made of di-iodotyrosine as a preoperative drug in such cases During the period of this investigation there were 6 cases in which iodine had been taken regularly for from 4 to 7 months In all cases success was obtained with di-iodotyrosine, typical pulse-chart is shown in fig 2 Subtotal thy ectomy in one stage was performed in 3 of the cases the remaining 3 being subjected to a two-stage operation There were no deaths among these patients There of course no proof that by stopping the iodine for a time and then instituting a further course a similar satisfactory state of affairs would not have obtained, but the uniform success with di-iodotyrosine suggests that there may be a real use for the drug in this type of case At the same time the indiscriminate use of iodine in the medical treatment of Graves's disease is to be deprecated most strongly

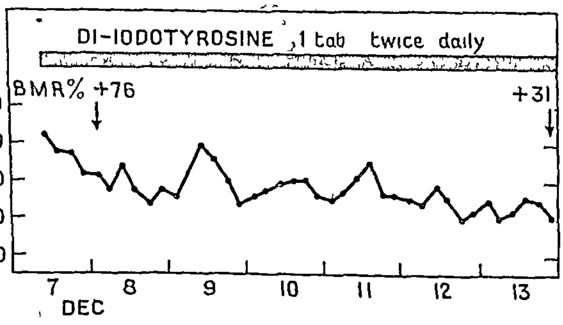

FIG 3—Four hourly pulse chart of man, aged 29, with primary Graves's disease, showing first remission produced with di iodotyrosine

Second courses of di-iodotyrosine—It is claimed for di-iodotyrosine that, if a remission has been obtained at a time when circumstances are unsuitable for surgical intervention, treatment can be stopped and then resumed at a later date when circumstances are more favourable There has been little opportunity to test this claim, but in 2 cases in which it was tried a successful second remission was obtained, allowing safe surgery to be performed in both cases The charts of one of these cases are shown in figs 3 and 4 If this finding can be substantiated it shows a definite advantage for di-iodotyrosine over iodine

Use over long periods—The use of iodine over long periods in the medical treatment of Graves's disease has been condemned It is claimed for di-iodotyrosine that such treatment is possible without harm to the patient, and that if surgery is required later further remission can be obtained by a combination of rest, sedatives and a further course of di-iodotyrosine or even iodine This claim is the chief recommendation for the use of di-iodotyrosine in the medical treatment of Graves's disease but I have made no attempt to investigate the pur medical treatment of the disease All the patients wh have come under survey have been those for whom surgery has been deemed advisable From the surgica point of view, however, there is a group of cases in which this claimed advantage of di-iodotyrosine might be useful Patients with Graves's disease often have to wait 6-9 months before they can be admitted to hospital fo surgical treatment In such patients the economi factor looms large and the ideal life of rest and freedom from domestic worries is far from attainable A drug which would keep the hyperthyroidism under contro during this waiting period and still allow of safe surgery at the end would be of great use It has so far only been possible to begin the investigations on this point A group of 12 outpatients have been treated in this way The regime adopted was to prescribe ½–2 tablets of di-iodotyrosine daily for three weeks according to the severity of the disease, then to omit the drug for a week repeating this cycle as often as necessary All 12 patients, when seen in the outpatient department, felt better for the drug and their pulse-rates showed a fall on successive visits In the 3 patients who were admitted to hospital during the progress of this investigation a satisfactory preoperative state was obtained by a further course of iodine (2 cases) or di-iodotyrosine (1 case) Subtotal thyroidectomy in one stage was safely performed in all 3 patients

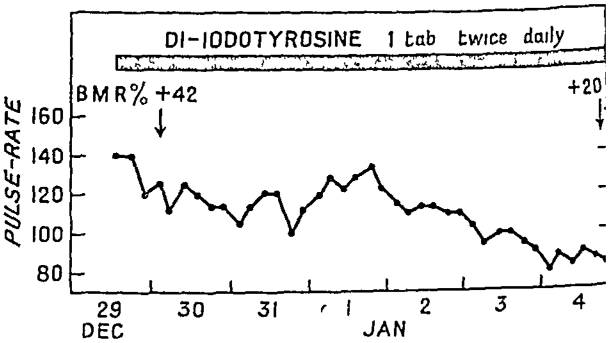

FIG 4—Four hourly pulse chart of the same patient as in fig 3 showing second remission produced with a further course o di iodotyrosine 16 days after conclusion of the first

Secondary effects—The administration of iodine to ne patients produces the syndrome of iodism, marked noises in the head, nasal catarrh and a rash The h is at first papular, later pustular, irritating and incon- nient, and as it often develops on the neck the opera- n field is involved Operation may have to be post- ned on account of it, so that the optimum period is ssed In 46 cases treated with iodine the only idence of iodism was a rash in 3 patients In all of ese potassium bromide had been administered as a dative concurrently with iodine Slesinger (1937) has inted out the undesirability of this combination In s experience rashes are much more common when romides are taken together with iodine, and he recom- ends Luminal as the best sedative for patients with raves's disease, to the complete exclusion of bromides n 31 cases given di-iodotyrosine there were no side ffects at all One patient was noticed to have a rash n the trunk several days after operation while still taking i-iodotyrosine, but this was diagnosed by a dermatolo- ist as pityriasis rosea No symptoms of iodism arose nd no iodine rashes were noted, even in cases to which romides had been given

CONCLUSIONS

Further work is required before the claimed advan- ages of di-iodotyrosine over iodine in Graves's disease an be accepted as fully substantiated It is hoped hat this paper will stimulate such work at other clinics Of the 70 cases of Graves's disease here studied 61 were perated on, and in most subtotal thyroidectomy was performed in one stage, a two-stage operation was per- formed in 6 cases on account of conditions arising during the first operation, in 2 cases only was preliminary arterial ligation considered necessary There was only 1 death in this series, postoperative pulmonary collapse leading to a fatal bronchopneumonia in one of the patients treated preoperatively with iodine There was no serious thyrotoxic crisis With such a satisfactory series it becomes even more difficult to assess the value of one method of treatment over another

SUMMARY

In previously untreated cases of Graves's disease, the use of di-iodotyrosine as a preoperative measure was restricted to the most severe cases In these it appeared to be entirely satisfactory, but showed no decided superiority over inorganic iodine

In patients who had had long courses of iodine before being referred to the surgeon, di-iodotyrosine produced remissions of sufficient degree to allow of safe surgery In this type of case the drug seems to produce better effects than can regularly be expected from iodine alone

In 2 cases a further remission was produced with a second course of di-iodotyrosine, but these figures are too small to allow of any definite conclusion

It seems to be possible to control the symptoms of hyperthyroidism by giving di-iodotyrosine periodically to patients awaiting operation, and still to get the patient into a good state for surgery when the time arrives In hospital practice the drug may be very useful in this way, and further work may prove it of value in the routine medical treatment of Graves's disease

No symptoms of iodism were produced by di-iodotyrosine

My thanks are due to Mr E G Slesinger and Mr Nils Eckhoff for allowing me access to their cases and for their encouragement and advice I am also indebted to Roche Products Ltd for providing the di iodotyrosine used in the investigation

DIABETES MELLITUS IN ADDISON'S DISEASE

EDWARD G G RHIND,
M B ABERD , M R C P.
MEDICAL FIRST ASSISTANT,
ROYAL INFIRMARY, SHEFFIELD

ANDREW WILSON,
M B , PH C , PH D GLASG
LECTURER IN PHARMACOLOGY,
UNIVERSITY OF SHEFFIELD

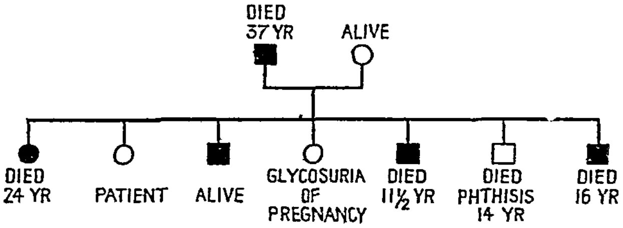
THE blood-sugar in Addison's disease is usually normal or occasionally subnormal (Kepler and Wilder 1938) and the occurrence of diabetes mellitus in association with Addison's disease is extremely rare Of 14 reported cases doubt has been cast on the diagnosis of 5 (Arnett 1927)

In 1926 Unverricht reported a case of diabetes and tuberculosis which later developed Addison's disease Arnett (1927) recorded the first well documented case of diabetes mellitus and Addison's disease A brief reference was made by Allen (1930) to 2 such cases seen at the Mayo Clinic, and another was reported by Gowen (1932) The onset of diabetes mellitus during the course of Addison's disease was described by Levy Simpson (1932), and by Crooke and Russell (1935) Rogoff (1936) reported a unique case of Addison's disease resulting from bilateral adrenal denervation in an attempt to cure diabetes mellitus

More recently an excellent description of the coincidence of diabetes mellitus and Addison's disease has been given by Bloomfield (1939)

CASE-RECORD

A housewife, aged 32, was admitted to the Royal Infirmary on July 25, 1939, complaining of dyspnœa, severe weakness and loss of energy which had gradually increased during the previous six months In the summer of 1938 she had noticed that her skin was darkening and becoming brown At first she thought it was sunburn, but the colour deepened throughout the winter She had lost over a stone in weight, but at no time had she any gastro intestinal disturbance Menstruation had always been normal There was no history of any previous illness She had been married eight years and had a healthy daughter, six years old A strong hereditary tendency to diabetes mellitus is shown in the family tree



Family history of patient Squares male, circles female Diabetics shown in black.

The patient was small, thin and very asthenic She was edentulous and weighed 7 st 2 lb There was generalised dark brown pigmentation of her body, particularly of her face, neck, dorsal surfaces of the forearms and hands, and the front of the knees The buccal mucous membrane was also pigmented A soft systolic murmur was heard at the apex of the heart, but there was no cardiac enlargement The blood-pressure was 102/62 , pulse rate 88, weak but regular There were no abnormal features in the lungs, abdomen or nervous system and no lumbar tenderness was elicited Urine albumin faint trace , sugar and ketones nil , deposit contained epithelial cells Blood sedimentation rate (Cutler) 15 mm in 1 hour , sugar 100 mg per 100 c cm , non protein nitrogen 34 6 mg per 100 c cm , chlorides (NaCl) 421 mg per 100 c cm , hæmoglobin 60% , red cells 4,130,000 , colour index 0 73 , white cells 6600 (neutrophil polymorphs 64%, eosinophils 5%, monocytes 2%, lymphocytes 29%) The blood picture was that of a mild hypochromic anæmia Fractional test meal and histamine test meal revealed complete achlorhydria Electrocardiogram and radiograms of chest and abdomen were normal

A diagnosis of Addison's disease was made, and the patient was given 5 mg of D O C A intramuscularly three times a week and ascorbic acid 100 mg daily The anæmia was treated with ferr sulph exsicc gr 3 and acid hydrochlor dil ℳ 30 three times daily She improved considerably and said she felt more energetic and less easily tired At the outbreak of war she was discharged from hospital She attended the outpatient department for a weekly injection of 5 mg of

Lancet

D O C A and continued to take ascorbic acid daily As she did not gain in weight her daily salt intake was augmented with 15 g of sodium chloride in cachets Her improvement was maintained and her weight increased, but she complained of backache and failing vision

On the night of June 13, 1940, she was readmitted to hospital on account of increased asthenia and persistent vomiting She said she had been quite well until the recent spell of hot weather but had been unable to attend the out patient department for a fortnight She had lost weight and the pigmentation had become darker She had no diarrhœa and micturition was normal On admission she was extremely asthenic and markedly dehydrated She vomited frequently and her breath smelled strongly of acetone Blood pressure was 58/40, pulse rate 112, regular , respiration rate 24 , temperature 97 8° F Urine sugar + +, acetone +, no diacetic acid Within the first 24 hours she received 25 c cm of Eucortone and 5 mg of D O C A intramuscularly and a litre of 5% glucose saline by intravenous drip In addition she was given intramuscularly 100 mg of vitamin C By the second day the vomiting had ceased and the blood-pressure had risen to 90/58 Daily treatment with 10 c cm of eucortone was continued and on the third day she was able to take 15 mg NaCl daily in cachets On June 20 the non protein nitrogen was 28 6 mg , chlorides 430 mg , sugar 660 mg per 100 c cm Urine sugar + , acetone and diacetic acid + , albumin trace

In view of the hyperglycæmia and glycosuria she was given 10 units of insulin morning and evening Glucose tolerance test gave the following result 0 hr 460, ½ hr 480, 1 hr 575, 1½ hr 600, 2 hr 565 , the dose of insulin was therefore gradually raised to 38 units in the morning and 22 units in the evening On June 26 her general condition had greatly improved and 5 mg of D O C A thrice weekly was substituted for eucortone The blood pressure now varied between 85 and 88 systolic and 56 and 60 diastolic, and the serum sodium had risen from 235 to 332 mg per 100 c cm Several attacks of hypoglycæmia ensued as a result of insulin treatment and the dose had to be reduced repeatedly A further radiogram of the chest and abdomen showed no abnormality A piece of pigmented skin was removed for pathological examination The report stated " Sections of skin show an increase of melanin pigment in the basal layer of the epidermis, but no evidence of iron in appropriately stained section "

By Aug 26 she had gained 5 lb , did not complain of any weakness, and was able to walk about the ward There was no change in her pigmentation and she had no recurrence of vomiting Her blood pressure was now well maintained at 92–94 systolic and 60–70 diastolic, and her serum sodium was 340 mg At this time her noon blood sugar level was 72 mg on the dose of insulin 28/20, and though at times there was mild glycosuria there was no ketonuria She was discharged on that date with instructions to take insulin 28/20 and to continue D O C A and salt treatment

As a result of a mistake in the dose of insulin given at home she was readmitted in the night of Aug 27 in a severe state of hypoglycæmia, and despite treatment with adrenaline and intravenous glucose she died in convulsions

AUTOPSY FINDINGS

Suprarenals —Both greatly reduced and each weighed 1 9 g The cortical cells in each zone were entirely replaced by fibrous tissue, which formed a fibrous capsule round the medulla The resultant width of the cortex was only a small fraction of the normal Round the periphery of the medulla there were some foci of lymphocytic infiltration Within the medulla were areas of focal necrosis in which the cells were large, swollen and stained pink and contained dark brown pigment granules in their cytoplasm In addition there were large focal collections of lymphocytes, but there was no evidence of tuberculosis Certain parts of the medulla were almost completely fibrosed

Pancreas —Slightly smaller than normal but no macroscopic changes on section Many of the islets of Langerhans were completely replaced by fibrous tissue Many of those still present were remarkably reduced in size and showed various degrees of atrophy and fibrosis No evidence of an inflammatory reaction

Pituitary gland —The anterior lobe was engorged and contained a small chromophobe adenoma about 3 mm in diameter There was obvious retention of colloid in the acini which were well formed and lined by chromophobe cells There were a few basophil cells in the acini Many of the chromophobe cells were larger than normal There was less than the normal quota of eosinophils, while the basophils were conspicuou few All three types of cells, however, appeared to be som what degenerated In Mallory-stained sections many of granular cells took on both the acid and basic stain, so th it was impossible to recognise transitional stages of the t types The posterior lobe presented no abnormal features

Thyroid gland —Smaller than normal, firm and devoid colloid The acini were lined by tall columnar epithelium an the histological picture was indistinguishable from that o Graves's disease

Thymus gland weighed 17 5 g and showed a considerab amount of fibrosis and fatty infiltration The remainin lymphoid tissue was hyperplastic

Skin and vaginal epithelium showed increase of melan pigment in the basal layer

Liver —Normal in size but flabby and pale owing to som fatty infiltration No hæmochromatosis

Lungs —Terminal bronchopneumonia No apical scars

The other viscera showed no significant changes

DISCUSSION

On her first admission our diagnosis of Addison disease was fully confirmed by the therapeutic respon to D O C A There was no evidence to show that t carbohydrate metabolism was disturbed at this stage the blood-sugar was normal and there was no glycosur or ketonuria, although the urine was examined on occasions In view of her history we diagnosed acu adrenal insufficiency on her second admission could attribute the ketosis to vomiting, but the glycosu and strong familial incidence of diabetes mellitus su gested the onset of diabetes Since her grave conditi would not permit delay for further investigation decided to treat the adrenal insufficiency immediate Some days later, when a diabetic response to the gluco tolerance test was revealed, the possibility of diabe coma or hæmochromatosis with ketosis was reconsider Although vomiting and dehydration, hypotension and low serum-sodium level are factors common to both ac adrenal insufficiency and to diabetic coma, the drama response to treatment with cortical extract is more favour of the former condition Indeed insulin was administered until nine days later, by which time patient had improved considerably Biopsy of the s disposed of the possibility of hæmochromatosis a further confirmation is provided in the autopsy rep

It is interesting to note that while the majority of authenticated cases of diabetes and Addison's dise developed diabetes first, our patient, despite the str familial tendency, presented diabetes only after Addiso disease had been established over a year A feature several of the cases has been " insulin hypersensitivit which has arisen with doses as small as 5 units insu In our case a maximum of 60 units of insulin per day administered before the first hypoglycæmic react occurred It seems worthy of note that, althou Bloomfield and Unverricht, whom he quotes, dem strated a decreased need of insulin as Addison's dise developed in their diabetic patients, we found t successful treatment of the suprarenal insufficiency not increase the insulin requirement of our patient

Much attention has been focused on the relations between the anterior lobe of the pituitary and the ot endocrine glands Numerous observations (Hewer 19 Kraus 1927, Harrop and Weinstein 1932) have been ma on the diminution of the basophil cells of the anter lobe of the pituitary in Addison's disease, and Crooke a Russell (1935) have suggested that this might accou for the hypoglycæmia The evidence presented by case does not seem to bear out their hypothesis , inde one of their own cases (case 9) is at variance with th deduction

SUMMARY

A case of Addison's disease is described in the cou of which diabetes mellitus developed Autopsy reveal atrophy of the suprarenal glands and of the islets Langerhans The pathological changes suggest th there is no relationship between the number of basop cells in the anterior lobe of the pituitary and the blo sugar level

We wish to express our thanks to Dr A Gurney Yates permission to publish the case, and to Dr L C D Hermi for the pathological report

PAIN IN ACUTE APPENDICITIS

RUSCOE CLARKE,
M B LOND, F R C S
FIRST ASSISTANT

MAX SHAPIRO,
M.R C S
LATELY HOUSE-SURGEON

THE DEPARTMENT OF SURGERY, BRITISH POSTGRADUATE MEDICAL SCHOOL

"The symptoms in the order of their occurrence may be mentioned as first, pain in the abdomen, sudden and severe, ollowed by (second) nausea or vomiting, even within a few hours, most commonly between three and four hours after he onset of pain, third, general abdominal sensitiveness, most marked in the right side, or more particularly over the appendix, fourth, elevation of temperature, beginning from two to twenty four hours after the onset of pain The symptoms occur almost without exception in the above order and *when that order varies I always question the diagnosis* If the nausea and vomiting or temperature precede the pain I feel certain that the case is not one of appendicitis "—Murphy [1]

"The first symptom in an attack of acute appendicitis is pain It is always pain, and never sickness or vomiting, nor malaise nor any other symptom whatever If pain should not be the inaugural symptom, in a case of acute abdominal illness, the possibility of the appendix being at fault may definitely be excluded "—Moynihan [2]

THUS Moynihan echoes the cry of Murphy with an added note of dogmatism, and this opinion is endorsed by many surgeons with wide clinical experience Zachary Cope [3] discusses the importance of the order of symptoms, which he gives as (1) pain (2) nausea or vomiting, (3) tenderness in the iliac fossa, (4) fever, and (5) leucocytosis While admitting that exceptions occasionally occur, he concludes that "if fever precedes the onset of pain, if vomiting accompanies or precedes the first bout of pain, it is generally not appendicitis with which we are dealing"

Recently we were almost persuaded to delay surgery in a case of acute appendicitis because pain was not the first symptom Within a few weeks we came across two other cases which departed from Moynihan's rule It is the purpose of this paper to suggest that while the order of symptoms is of importance in the diagnosis of acute appendicitis it is dangerously misleading to suggest that pain always comes first

CASE-RECORDS

CASE 1—A male clerical worker, aged 32 Admitted to hospital at 4 15 P M. on Dec 10, 1940, complaining of nausea, vomiting, dizziness and abdominal pain Before this illness he had had occasional indigestion but no previous attack of abdominal pain At about 9 P M on the 8th he began to feel "bilious," experiencing nausea and a desire to vomit He was inclined to blame some fish which he had eaten a little while before Half an hour later he started shivering, nausea returned and he tried to vomit He then went to bed After this the pain began, in the centre of the abdomen During the night it shifted to the right iliac fossa, where it remained until his admission to hospital He vomited three times in all His bowels opened twice after taking castor oil on the day before admission. He was seen by his doctor 24 hours before admission, when he made a tentative diagnosis of gastro enteritis The decision to come to hospital was made by a medical relative who had become anxious at the delay

He was well built and well covered, with a healthy complexion His tongue was coated and his breath fœtid The abdomen moved freely on respiration, and there was no rigidity or guarding of the abdominal muscles There was definite tenderness in the right iliac fossa, especially towards the loin On rectal examination there seemed to be a tender mass high up on the right The other systems revealed no abnormality Temperature 97 8° F, pulse rate 80, respirations 20, blood-pressure 120/80 Retrocæcal appendicitis was diagnosed

Operation under gas, oxygen and ether McBurney muscle splitting incision On opening the abdomen no free fluid escaped The appendix was retrocæcal, adherent to the cæcum and posterior abdominal wall It was delivered with difficulty and removed base first, without inversion of the stump A generalised ooze necessitated leaving in a rubber drain down to the stump The wound was closed with interrupted catgut and silk-worm gut The appendix was thickened and intensely inflamed with a large gland in the meso-appendix On section it was found to be full of pus

The post-operative course was uneventful Discharged on the 13th day Wound and sinus firmly healed by the 20th day (Dec 30)

CASE 2—Female factory worker, aged 19 Admitted to hospital on Jan 13, 1941, complaining of vomiting and pain There was no history of any previous alimentary upset or abdominal pain In March, 1939, she had been treated for a mild anxiety state Although this was related to conditions of work in the factory, other factors were involved Mild psychological treatment was arranged and considerable improvement resulted She began to experience nausea and general malaise 48 hours before admission Soon after this she vomited several times Some hours later she began to complain of colicky but not severe abdominal pain Several hours before admission this became greatly intensified and generalised over the whole abdomen

The patient looked ill Her breathing was entirely thoracic The abdomen was tender and rigid all over The flanks were dull to percussion The diagnosis lay between strangulation of uterine adnexæ, ruptured ectopic gestation or perforation of a hollow viscus

Operation under gas, oxygen and ether Right lower paramedian incision On opening the abdomen a large quantity of free fluid escaped The intestine was covered with flakes of lymph The appendix, which was distended, inflamed and perforated, was removed The pelvis was drained through the lower end of the wound

For several days she ran a swinging temperature accompanied by tenderness in the flanks and signs of fluid in the chest These last persisted for several weeks but later subsided She was discharged on Feb 18 The wound had healed and the chest signs had almost cleared

CASE 3—Housewife, aged 60 Admitted to hospital at 9 10 P M on Feb 2, 1941, complaining of vomiting and abdominal pain There was no history of previous indigestion, but on close questioning after the operation she admitted that she had suffered from short mild attacks of upper abdominal pain She did not remember when the last one had been She had never vomited or experienced pain anywhere else in the abdomen She was quite well up to 36 hours before admission The first symptom was malaise, followed by fainting and vomiting She vomited three times and fainted four times She then went to bed and slept She began to have twinges of colicky pain in the upper abdomen 19 hours before admission, and 6 hours before admission this pain suddenly became very severe and centred around the umbilicus, 4 hours before admission it shifted to the right iliac fossa There was no further vomiting The bowels had opened after a dose of salts which were taken after the onset of pain There were no other symptoms

She was a pale, frail, coöperative woman in no obvious distress The tongue was coated The lower abdomen was moderately distended There was some tenderness in the right upper quadrant and obvious tenderness in the right iliac fossa, with persistent but slight muscular guarding in the right lower quadrant On rectal examination no mass could be felt, but there was tenderness high up on the right Auscultation of the chest revealed coarse rhonchi Blood-pressure 140/70, temperature 99° F, pulse rate 90, respirations 20 The remainder of the examination was negative The diagnosis made was probable acute appendicitis, ? carcinoma cæci

Operation under gas, oxygen and ether Right paramedian incision With the patient's muscles relaxed it was possible to feel a mass high up in the right side of the abdomen at the level of the umbilicus, it was about the size of a tangerine and freely mobile On opening the abdomen the mass was found to consist of omentum and gut surrounding the appendix On gentle separation of the inflamed appendix a small abscess was opened This contained a fæcolith which was lying against the under side of the terminal ileum An area

in the wall of the ileum was ulcerated and almost perforated The appendix was gangrenous and the fæcolith had obviously come from a perforation at its base The appendix was removed, without inversion A drain was left in down to the region of the ulcerated ileum and brought out through a stab wound in the right iliac fossa

The postoperative course was complicated only by a small subcutaneous abscess in the upper part of the wound

On naked-eye examination of the appendices removed, those from cases 2 and 3 showed definite obstruction to the lumen with perforation In case 1 no localised organic constriction was demonstrable although the appendix was distended with pus

DISCUSSION

In case 1 nausea and shivering preceded the onset of abdominal pain by several hours This story, added to the patient's conviction that fish had upset him, probably encouraged his doctor to make the diagnosis of gastro-enteritis In view of the use of castor oil in early cases of gastro-enteritis, this point of differential diagnosis is extremely important At a later stage the absence of abdominal spasm, by no means unusual in retrocæcal appendicitis, even when well advanced, might have led to the institution of expectant treatment In case 2 the onset of pain was preceded by several hours of nausea, general malaise and vomiting There was no history of any previous attack Questioned after recovery, the patient seemed to be a reliable witness and the original story was confirmed The history of a mild anxiety state may or may not be relevant , psychoneurotics sometimes have a high threshold to the pain of an acute unfamiliar pathological process In case 3 pain was preceded by 17 hours of malaise, fainting and vomitin and it seems unlikely that perforation, abscess formation and ulceration of the ileum all took place in the tim which elapsed after localisation of the pain in the ili fossa—i e , 4 hours The appearances at operation wer more compatible with the 36-hour story

In only one of these three cases was there any histor of previous indigestion, and only in case 3 was there history of previous attacks of abdominal pain This i significant because many have maintained that recurren attacks of appendicitis are likely to be atypical and tha therefore the order of origin of symptoms as describe by Murphy is only of value in first attacks Neith Murphy nor Moynihan make any such differentiation

All three patients were carefully questioned aft recovery, and all insisted that pain was not their fir symptom In case 2, laparotomy was clearly indicate whatever the diagnosis Cases 2 and 3, however, cou justifiably have been treated conservatively if appendi itis could have been excluded This we believe to the danger of a too rigid acceptance of the Murph Moynihan dicta

SUMMARY

In 3 cases of acute appendicitis here described pa was not the first symptom, and it is concluded that t dictum that pain is always the first symptom is misleadi and may lead to dangerous delay in operation

We have to thank Mr A K Henry for his interest a advice, Mr Douglas for permission to make use of t particulars of case 2, and Dr Allon Daley, chief medi officer of the L C C for permission to publish the three cas all of which were treated in Hammersmith Hospital

Reviews of Books

Abdominal Operations

By Rodney Maingot, F R C S , senior surgeon to the Southend General Hospital and the Royal Waterloo Hospital London D Appleton Century Company 2 vols Pp 1385 £5

This book is planned on the same lines as Moynihan's well-known volume It is a comprehensive work dealing not only with the general surgery of the abdomen but with such rare procedures as partial pancreatectomy, and for these valuable references to the original sources of information are given Every aspect of abdominal surgery is included—the preparation for operation, the advisability of operation, the difficulties of the actual task, the details of each stage, the after-treatment, the likelihood of success, the complications which may arise, and the causes of failure—so that the book is both a guide to the actual operation and a thoroughly useful work of reference to novice and experienced surgeon alike When there are several methods to choose from one is always wisely labelled as the standard operation There are very few omissions, none of generally recognised procedures , those few which can be noted seem to have been made deliberately as the result of Mr Maingot's experience In the account of the abdomino-perineal resection of the rectum the pathology insisted upon by Miles is accepted without reserve, and the operation made needlessly extensive in consequence It is generally agreed now that in the stage of resectability there is no lateral and downward spread of the malignant growth But it seems hardly necessary to have included accounts of cholecystogastrostomy, or of simple excision for gastric ulcer, since these procedures, condemned by the results, are no longer employed The illustrations are extremely well drawn and reproduced, and have the welcome quality of depicting clearly the meaning of the text

An Agricultural Policy for Britain

and a Policy for British Agriculture By G Goddard Watts London G Allen and Unwin Pp 38 1*s*

This well-written booklet is calculated to hold the attention of the reader whether he is agriculturally minded or not In this it fulfils one of its main objects, which is to educate public and political opinion in the importance of preserving a thriving agricultural community after the war , and it demonstrates to farmers that they can win over the townsman by dispelling t view that all farmers are grumbling inefficients who a never satisfied with their lot, however much the Gover ment may do for them The author has many sensi suggestions to make on the maintenance of soil fertili He examines the changes which have taken place agriculture since war broke out, and pleads that t extended use of the plough is a thing worth keeping when peace comes He has the same hope about so of the improved marketing and educational syste which have recently been adopted It would hardly possible to get unanimity on such a controversial s ject as a policy for agriculture , it is evident that so of Mr Watts's arguments are open to criticism a would not meet with approval from some agricultu economists Occasionally he makes claims which would be hard to substantiate, such as " It is a tradit that three generations away from the soil will exha the vitality of the family and that for re-vitalisati that family must leave its urban surroundings a re-establish itself in rural life " But if he is somewh opinionated, he has clearly had wide experience in bo educational and farming circles, and is entitled to expr definite views

Office Clinical Chemistry

By Emanuel M Abrahamson, M D , adjunct attendi physician, Jewish Hospital of Brooklyn , assista attending physician and chief of the diabetic clin Greenpoint Hospital London Humphrey Milfo Oxford University Press Pp 245 25*s*

As its title suggests this book is primarily for the u of practitioners who wish to carry out their ow investigations in clinical chemistry It is compact a simple enough for the beginner to follow easily, but nevertheless comprehensive and successfully covers mo of the standard tests Dr Abrahamson introduces tw ideas which the unpractised reader will find particular helpful one is the presentation of methods of analysi step by step, in illustrated form , the other is a chapt devoted entirely to the preparation of each reage mentioned throughout the book Many of the we known methods have been modified by the author fro his own experience The changes are all towar simplification of technique and economy in the use apparatus The field to be covered is so wide that the are bound to be some omissions—for example, there is mention of fæcal analysis Nevertheless the book will a stand-by to doctors interested in clinical chemistry

THE LANCET

LONDON SATURDAY, JULY 12, 1941

PREMARITAL AND PRENATAL TESTS

Legislation in the United States requiring comulsory examination to exclude venereal disease in andidates for marriage and expectant mothers has ivided American doctors into heatedly opposed amps Oddly enough it is the experts who are the main opponents of state interference They point out that legislation has put too much reliance on blood-tests, for many patients with positive reactions may be congenital syphilitics or have passed into the non-contagious state They cast doubts on the hundred-per-cent reliability of any particular test or combination of tests, and suggest that healthy people may be thus penalised They hint that the mere suggestion of compulsion may drive treatment underground They talk of hasty legislation, the liberty of the subject and professional secrecy On the other hand, public-health authorities have pointed out that any case of unsuspected syphilis discovered and treated is a gain to the nation, and theoretical objections should therefore take second place The statistics are difficult to interpret and liable to gross error, since only positive reactions and not proved cases of syphilis can be shown, and the number of infectious cases is not indicated But certain facts do emerge[1] Out of nearly 680,000 examinations during the years 1936–40 in thirteen states, 9000 were positive, a proportion of 1 3% At first a large percentage of those found to give a positive reaction were not aware of their syphilitic taint, and it became noticeable that the proportion of positives diminished yearly with the increased awareness of the implications of the tests, suggesting that those suspecting they might give a positive reaction avoided examination In West Virginia, for example, during the first six months after legislation became operative there were 4 2% positives in 1600 cases, whereas in the next twelve months the percentage dropped to 2 4 Opponents of legislation seized on these figures eagerly To the credit of legislation, it was found in New Jersey that of 206 candidates for marriage who gave positive reactions and were refused certificates 71 gave up marriage, 18 married outside the state, and 135 were found three months later to be undergoing treatment for the condition Prenatal tests are carried out in nineteen states under varying conditions which De Porte summarises on another page, the responsibility resting in some on the medical attendant, in others on the patient There are no penalties for non-compliance, the requirements as to time and manner vary considerably, and no figures are likely to be available for years as to the preventive results gained It is, however, a very important experiment if carried out with any thoroughness, for syphilis in women is much more serious for the next generation than syphilis in men A man treated adequately is almost certainly not a transmitter A woman treated adequately and giving a negative blood reaction is still capable of transmitting the disease to the next generation unless treated again during each succeeding pregnancy Syphilologists are probably inclined to take too rigid a scientific view of compulsory examinations owing to their preoccupation with the individual, public-health authorities are inclined to ignore the psychological reactions of individuals There is much to be said on both sides But the public conscience is slowly awakening to the less obvious perils of venereal disease, and it is unlikely that attempts to remedy known perils by legislation will diminish These experiments by individual American states are likely to become more and more elaborate, and we in this country will watch them with the keenest sympathy

RASPBERRY-LEAF TEA

Infusions have always found an honoured place in the pharmacopœia of the lay public, and across the Channel there is a *tisanerie* attached to hospital dispensaries where leaves and flowers are made into pleasant drinks. Herbal teas are legion, and include such favourites as elder, camomile, peppermint and dandelion, the selection depending mainly on the flora of the district In general, the physician grudgingly ascribes whatever pharmacological actions herb teas possess to their contained volatile oils, and their curative action, if any, to the water The beneficial effects of the treatment are held by herbalists to be directly proportional to the volume of fluid consumed, and the unbeliever urges that when allowance is made for the salutary effects of intermittent douching of the stomach, and for the dietetic restrictions which usually accompany this form of therapy, there is little need to claim special virtue for the vegetable basis Moreover, the patient is likely to benefit from the holiday he must allow himself in order to cope with the resulting diuresis But doctors have been too much inclined to sit in the seat of the scornful Instances are not lacking to show that the old wife's tale may have a germ of truth in it William Withering did not disdain to take an interest in the medical folklore of the midlands, and out of the crudities of the unsophisticated he fashioned one of the masterpieces of medical literature The case of ergot is on a different plane, but the same principle is apparent For many years practitioners continued to use the liquid extract of ergot in childbirth and as a preventive against postpartum hæmorrhage, despite the assertions of pharmacologists that the preparation must be inert because it contained little or no ergotoxine The subsequent isolation of a new alkaloid, ergometrine, vindicated the practical obstetrician In our columns last week Prof J H Burn and Mr E R Withell described a substance in raspberry leaves which relaxes uterine muscle This paper is obviously merely a beginning of the research which will follow on the pharmacology and therapeutics of the active principles of *Rubus idæus* Controlled observations on the human subject will be necessary before we can say whether raspberry leaf does in fact make parturition "easy and speedy," as the herbalists maintain The findings of Burn and Withell justify thorough clinical trial If raspberry leaf, which apparently causes relaxation of plain muscle, proves to be effective in shortening labour, we shall be faced with the paradox of an ecbolic action in a drug which diminishes uterine tone Much depends on whether

---

[1] See Sheppe, W M *J Amer med Ass* 1941, 116, 2006

it has a relatively stronger action on the lower than the upper uterine segment It seems possible that the popular claims on behalf of raspberry leaves are only partly justified, the mother of a large family is apt to remember her labours as either "difficult" or "easy," by which she means painful or not painful, rather than in terms of their length This work opens up the whole question of the obstetric use of drugs which relax involuntary muscle Thus, if the active principle of raspberry leaves is in fact therapeutically valuable by virtue of its power to cause muscular relaxation, other drugs having the same pharmacological action may prove to be even more effective, and it might be useful to study the effects of the slowly acting nitrites, the Trasentin group of compounds and even the almost forgotten essential oils

NON-INFECTIVE LEUCOCYTOSIS

WE all know that polymorphonuclear leucocytosis accompanies many infections, but the fact that it occurs in other states is less familiar These non-infective leucocytoses are characteristically short-lived and before dealing with them the question of daily variation must be mentioned Opinion now inclines to the view of HARVEY and HAMILTON,[1] that although there are daily variations they are insufficient to upset the usefulness of the ordinary leucocyte count SHAW[2] has shown that there is a definite diurnal leucocytic "tide," setting towards a flood in the afternoon or evening and an ebb in the early morning, there are other small oscillations but they are unimportant One of the earliest observations on the leucocyte count was the rise after food—the digestive leucocytosis—but the afternoon tide, which occurs whether food is taken or not, probably accounts for most of this Transitory leucocytoses have been described after experimental meals, especially if unusually hot or cold or irritant, but the cause here is hardly digestive, and individual variation is considerable Exercise causes rapid leucocyte variations Short bouts of severe exercise, or prolonged efforts like Marathon races, may increase the polymorphonuclears as much as 300% and the count may not return to resting level for some hours afterwards MEDLAR[3] has found, however, that mild ordinary exercise does not cause variations outside the normal range, so that it is unnecessary, for example, to rest a patient for half an hour before taking a leucocyte count because he has walked up a flight of stairs Epileptic convulsions may be followed by counts of 40,000 cells per c mm, mostly polymorphonuclears A curious leucocytosis is that which may accompany emotion, and WITTKOWER[4] was able to induce it by suggesting joy, sorrow or rage to hypnotised patients even when the patient remained quite still COHEN and WARREN[5] induced artificial fever in relatively normal patients for periods of 4–21 hours, this was accompanied by a definite polymorphonuclear leucocytosis that declined rapidly when the fever was allowed to subside The fact that adrenaline causes a leucocytosis might provide a partial explanation of these changes The leucocytosis produced by adrenaline is less exclusively polymorphonuclear than in exercise and was thought to be due to contraction of the sp expelling cells into the blood-stream, but furth experiment in man and animals showed that leucocytosis appeared just the same when the sp had been removed The exceptional rise in ly cytes has been traced to an increased flow of lym and possibly to contraction of lymph-glands

GARREY and BRYAN[6] came to the conclusion th the common factor linking these various causes leucocytosis was that they all involved changes the distribution of leucocytes among the tissu There is now a good deal of evidence to show th leucocytes collect in the capillary blood vess especially those of the lungs and liver and to a l extent the spleen Here they may lie in the marg of the blood-stream and remain to all intents out the circulation, this mechanism, when exaggerat has been shown to account for the leucopenia allergic and allied states[7] The granulocyte form tissue of the bone-marrow plays no part immature cells do not appear in the blood—grad replenishment rather than quick mobilisation is function of the marrow Exactly what calls leucocytes from their resting-place in the capilla and to what site of action they are hurry is not yet clear and it is hard to deduce answers from studies of changes in the blood str alone

Perhaps the most important, from the pract point of view, of these non-infective leucocytose that which accompanies labour and is prolonged some days into the puerperium It has been kn for nearly 90 years, and WOLFF,[8] in a re re-examination points out that it follows a def pattern, the rate of increase of the leucocytes b related to the uterine contractions, and the prog of labour, reaching a maximum at delivery leucocytosis is greater in primiparæ than multip Counts of 20,000 per c mm are common and u 40,000 have been recorded, but after about a week count returns to normal The practical importa of this leucocytosis, as GIBSON[9] has remarked, is in the puerperium single white-cell counts show a high number of polymorphonuclear cells do indicate infection The count must be repeated if it is rising or maintained infection should be loo for, but if it is falling a high count may wel physiological WOLFF attributes this leucocyt of labour to the uterine contractions, but other fac must also be considered Labour involves cont tion of voluntary as well as smooth muscle, t must be considerable circulatory readjustments, emotional changes are surely present As we l seen, all of these can cause leucocytosis, but transient leucocytosis limited to their period of act whereas the leucocytosis of labour is continued the puerperium and takes days to subside GIB therefore suggested that the hormonal changes kn to be prominent in pregnancy and after labour affect the leucocytes and are at least partly res sible Support for this view is given by the occasi presence of immature granulocytes, the slight le cytosis of pregnancy, and the fact that the b marrow shows hypertrophy of the granuloc ing tissue during pregnancy[10] All observers have d that when uterine contraction is weak the rise hite cells is slow, and if uterine inertia develops leucocyte level rises no further There is thus ence that the leucocytosis of labour is related to other non-infective leucocytoses we have men-ied, but it stands in a class by itself as being partly to redistribution and partly due to true increased mation of leucocytes in the bone-marrow

THE WATCH ON THE THAMES

THE last war gave London chlorinated water It worth looking back to that time, for the advances ide then have served us well for more than twenty-e years At one time it was suggested that ondon should get its water from the mountains of ales, following the example of Liverpool and rmingham, and of Manchester watered from airlmere, and Glasgow from Loch Katrine But orrowed water for the population of London would ave been no small draft on the resources tapped , nd it was decided more fairly that London should rink from the Thames and the Lee, from its own eep borings into the chalk, and from those streams nd springs of Essex which were led together as nother river, the New River Undoubtedly a pure ource is best, but if this is not available the aim must e to make a polluted supply safe and 80% of the ondon water-supply is derived from rivers either irectly or indirectly polluted with sewage and likely to become still further polluted with the increase of population In 1916 London was drinking river water purified by standing in huge reservoirs and then passing through filter beds The raw waters of the Thames and Lee contained coliform bacilli in undesirable numbers, but fæcal streptococci were rarely found and pathogenic bacteria were so few that there was no chance of them surviving the sequence of storage and filtration which removed 98% of suspended bacteria The method was thus perfectly satisfactory , but the war was in progress and the price of coal rising To pump 70–80 million gallons of raw Thames water daily into reservoirs was not only costly but was using coal needed for other national ends The Metropolitan Water Board was faced with a problem and an opportunity , HOUSTON rose to the occasion and boldly experimented with large-scale chlorination He proved that by adding chloride of lime (bleaching powder) to river water it was possible, without providing for settling, to obtain water as bacteriologically pure as that stored in Staines reservoir During the summer of 1916, the 75 million gallons were treated in this way The cost of introducing 0 5 part of available chlorine into 1 million parts of water was 3*s* , compared with the 13*s* which was the cost of coal to pump the same amount of water into reservoirs , this meant a saving of £260 a week Since that time London has drunk chlorinated water and liked it

In this war the board has faced and overcome the problems of mains damaged by high explosive and has shown how mobile chlorinators could be used to deal with local contamination The amount of chlorine needed was as much as 10 parts per million, but the results were effective and there has been no epidemic of the enteric group of fevers in London during the past winter The Londoner in fact feels so safe about the purity of his water, whatever he may feel about his milk or his beer, that he is quite content to leave it to the Metropolitan Water Board, asking no questions But there are very good reasons now why all the health authorities in the area should be water-conscious and prepared not only to meet but to forestall any alarms and excursions that may await us For this reason Lieut -Colonel E F W MACKENZIE, director of water examination, has asked the board to arrange for a consultative medical committee to be set up to bring about a closer liaison between himself and the medical profession, and to advise on matters of broad policy The committee, which will have Lord HORDER as chairman, will include representatives of the London School of Hygiene, the local branches of the Society of M O H 's, the Royal Sanitary Institute, and the medical profession in London The committee is appointed in the first instance for the war period, but we may hope that such cooperation will survive into the peace

---

Annotations

NATIONAL WHEATMEAL

A NOTICEABLE feature of public announcements by the Government during this war is their advisory as distinct from compulsory nature If it is desirable that people *should use less of some commodity they are asked not* commanded, to dispense with it Only in the last resort is compulsion used, and then only if there is a reasonable prospect of obtaining more that way than by the continued application of gentle persuasiveness A time does come however, when in the common interest it may be advisable to compel the slack and the listless to come into line with good citizens That point has not yet been reached in the campaign against diphtheria, but the Ministry of Health may well feel they are in a stronger position as custodian of the nation s nutrition Lately the Ministry in circular 2407 has called the attention of hospitals to the " desirability on nutritional grounds of making available to patients and staffs within the Emergency Hospital Scheme and to inmates and staffs *of any other residential institution under the control of* local authorities, bread made of national wheatmeal flour " The circular goes on " The Minister has been in consultation with the Minister of Food on this matter and he is advised that national wheatmeal flour is now available to bakers " We all know that the national wheatmeal is advisable on grounds of saving shipping space and of the welcome increases it would bring of our intakes of the vitamin-B complex, vitamin E and iron Its only drawback is its inhibiting effect on calcium intake, which can be remedied by adding calcium carbonate, though, as Kent Jones pointed out in our columns,[1] there may be some technical difficulties to be overcome there Whatever the Minister of Health is advised, however, any member of the public could tell him that there has been some stop somewhere in the supply of national wheatmeal flour Whether the obstruction lies with the milling industry, the master bakers or the public there is no doubt that in many places wheatmeal flour is not " available " , the stuff is not there Is it not time for the Minister to see that it is ?

HETEROGENOUS GRAFTS

AT one time it was thought that the difficulties of replacing damaged tissues by grafts from another person or animal were simply ones of technique and that as soon as a circulation could be established between the implanted tissue and the host heterogenous grafting

---

Pitts, H H and Packham, E A *Arch intern Med* 1939, 64, 471

[1] *Lancet*, June 7, p 731

would become a practical procedure But the work of Loeb,[1] Little and Johnson,[2] Bittner,[3] and Gorer[4] has made it clear that the main obstacle in the way of obtaining persistent grafts is genetic incompatibility between donor and host which results in an antibody response on the part of the host, it is this reaction that is responsible for the destruction of the graft The number of antigenic factors that may work in this way is very large, and when an attempt is made to graft tissues within a genetically heterogenous population it is like giving a blood transfusion if there were some thousands of groups instead of four Soviet experiments have lately given a new impetus to this work Filatov[5] has claimed great success with grafts of cornea, and it is possible that a really persistent graft may be obtained in some cases The substances released during the destruction of the graft may, however, have a strong stimulative effect on tissue regeneration, and Miagev and Tushinov have given evidence to support the idea that so far as endocrine organs are concerned this stimulant effect may act more or less specifically on a depressed or undeveloped gland The fact that replacement of a limb by transplantation is not impossible from a purely surgical point of view has been shown by Shwind in America and by Lapchinski,[6] a pupil of Filatov, both of whom worked with rats Lapchinski obtained some striking results with grafts between young litter mates, but although he did not use pure lines of rats it must be borne in mind that laboratory animals are much more inbred than any civilised human community, the odds against obtaining a really successful graft in human surgical practice are very great indeed

TRANSMISSION OF ANTIBODIES FROM MOTHER TO CHILD

THE infant acquires antibodies from its mother either during intra-uterine life through the placenta or after birth through the colostrum, and the relative importance of these two routes in different species of animals varies according to the number of layers of tissue interposed in the placenta between the maternal and fœtal circulation Mason, Dalling and Gordon[7] summarise the facts as follows —

Species	Layers between maternal and fœtal circ	Importance of—	
		placenta	colostrum
Pig	5	–	+ + +
Ruminants	4	–	+ + +
Carnivores	2	+ –	+
Rodents, apes, man	1	+ + +	+ –

In man, therefore, the colostrum plays a minor rôle in transmission, and according to Kuttner and Ratner[8] its ingestion does not increase the antibody content of the blood stream in the human infant at all Lately Liebling, Youmans and Schmitz[9] of Chicago have studied the occurrence of diphtheria antitoxin in the human pregnant mother, newborn infant and the placenta In 11 non-immunised, Schick positive mothers no change was found in the antitoxin titre of the serum during the course of pregnancy, and they gave birth to infants who were Schick positive and whose anti level was as a rule equal to that of the mother On other hand, 17 non-immunised, Schick negative (or some instances "partial positive") mothers all rise in the antitoxin content during pregnancy, the in titre may be attributed to the small amount of in the Schick dose acting as a "secondary stimulus" immune or potentially immune people[10] The antitoxin level of the infants of this group was always higher th the preliminary antitoxin level of the mothers In 1 non-immunised, non-Schick-tested mothers there was rise in antitoxin titre during pregnancy From the observations it is clear that when the mother posse natural antitoxin its transfer through the placenta wi provide her newborn infant with a temporary pas immunity Further, the mere Schick testing of th pregnant mother possessing natural antitoxin will usuall act as a stimulus to increased antitoxin production and may provide a greater and more prolonged protection to the infant after birth In another series of experiment made by Liebling and his colleagues, 14 Schick positive and 20 Schick-negative (or partial positive) expectant mothers were actively immunised with diphtheria toxoid and almost all of them showed a satisfactory response in the formation of antitoxin Most of the infants born to these actively immunised women gave negative Schick tests and had an antitoxin titre equal to that of their mothers at term It is thought that the transfer of an enhanced titre from an actively immunised mother to her infant will provide a more lasting passive immunity in the newborn, but the Chicago workers are uncertain whether they have succeeded in the active immunisation of the fœtus in utero by actively immunising the pregnant mother, they hope to learn more about this question by following the antitoxin titres of the infants for one or two years Finally they estimated the antitoxin in placental extracts (prepared by McKhann's method) of 8 non immunised Schick-positive, 13 non-immunised Schick negative, 13 immunised Schick-positive, and 16 immunised Schick-negative mothers Very little diphtheria antitoxin was detected in any of these titrations and what there was could usually be accounted for by the retention in each placenta of a small amount of fœtal and maternal blood They therefore suggest that the protective value of the placental extracts now used extensively in the prophylaxis of measles, may depen merely on the residual placental blood, which, a McKhann[11] directs, must not be removed from th placentas before extraction Liebling and his colleague apparently did not encounter the well-recognised ski insusceptibility of infants to various toxins to whic attention has been directed by Okell[12] and others, an which leads to serious discrepancies between the result of skin tests and the presence of antitoxin in the blood in children under six months

Most of the evidence for the placental transmission of antibodies has been obtained from the study of diphtheria and scarlet fever antitoxins in man, but all other antitoxins and protective substances (e g, whooping cough antibodies) are probably also transferred by this route More work needs to be done in man and animals on the duration of passive immunity, maternally conferred and thus of homologous type Experiments on guineapigs indicate that in them the loss is 25% per week and that the titre reaches 1/10 of the original value eight weeks from birth It is noteworthy that the serum of certain animal species—ruminants, for instance—is deficient in globulin, and this deficiency may be associated with the inability of the antibody-forming aratus to respond adequately to an antigenic stimulus ing the earliest period of life. In man, Blum,[13] ne Jakobkiewicz and others have noted the compara- e failure of young infants to produce diphtheria ntoxin after the injection of toxoid and this is one son why diphtheria immunisation is not recommended a general rule till after the sixth to ninth month. hooping cough vaccine is seldom administered in the nited States till the seventh to tenth month, although S Wilson,[14] being impressed by the high mortality nder six months, advocates beginning the course at the d of the second or third month. In view of the certainty of response at this early age it would perhaps e wise to insist on further injections of vaccine in later fe for these children, to re stimulate their antibody- roducing mechanism.

IMPROVING BLOOD-GROUPING

WAR-TIME activity in blood-grouping has drawn ttention to the lack of uniformity in nomenclature and echnical methods in use among those making the tests. paper by the Imperial Serologist in India and his olleagues[15] teems with suggestions for revising and tandardising practice. A worker adopting their pro- osals would have to revise his methods drastically nd his new methods would not necessarily be better han his old, but his diagnoses of blood-groups would lmost certainly be much more accurate because he vould determine not only the antigen content of a erson's red cells but also the antibody in the serum. None of the authorities omits, unless he must, the check- est offered by examination of the serum, for following-up ny anomaly should prevent all errors in diagnosis of the ABO system. Before the war nearly all clinicians used the Moss numerical classification, but more and more of them are taking up the international alphabetical ABO nomenclature, and the use of letters for the antigens and of "anti-A" and "anti-B" for the agglutinins seems satisfactory and logical. To get established workers in a field to adopt a new terminology is difficult, as anatomists and bacteriologists know; and, since the great advantages of letters over numbers are being recognised and letters are being used, nothing should be allowed to interfere with the adoption of the international classification as it stands. Some major alterations in the alphabetical notation suggested by the workers in India would not be improvements. The use of the lower case "a" and 'b' for the antibodies is reactionary and was rightly condemned years ago. The Greek α and β for the antibodies are said to be unnecessary—and indeed they do not appear in the recommendations of the League of Nations Committee responsible for the international classification—but well-known workers in the field use them and would miss them, and they have no obvious disadvantages. The terms "isogen" and "isonin" proposed for the isoagglutinogens A and B and their isoagglutinins might be accepted by some, but "hæmogens" M and N for the antigens of the M N system of groups would be hard for anybody with a regard for etymology to tolerate. Much has been written mostly in America about the harm that may theoretically befall a transfused patient if the antigen in his red cells meets corresponding antibody in great strength in the donor's plasma. The practice recently introduced of treating shock with transfusions of large amounts of blood serum or plasma or with concentrated serum or plasma, has similar possibilities. It is difficult to discover from the literature how real and how great this danger is, but the workers in India attach considerable importance to it, and believe that accidents following indiscriminate transfusion with group O have escaped detection. In their technique the strength of the antibodies in the sera of O donors is determined and the donors are classified accordingly; quite a large proportion are not accepted as universal donors because the antibody content of their serum is considered to be dangerously high. Colonel Greval strongly advocates direct tests of the reactions between the blood of the recipient and that of a prospective donor, whether of the same or of another group. He is right in urging that there is room for improvement in grouping procedure; more should be demanded of a technique than that it should be rapidly and easily performed.

POSTURE AND THE T WAVE

THE T wave, that problem child of electrocardiography, has in recent years taken one of its excursions into the realm of clinical and physiological research. We are still more or less ignorant of its significance and cause, but information is accumulating. One of the earliest facts known about it was that it altered with changes of posture, becoming inverted when the subject stood up. This inversion has been attributed by some to orthostatic anæmia of the heart, or to a faulty myocardium, while others regard it as normal. Scherf and Weissberg[1] have been at the puzzle again. Of the 35 subjects, aged 20–30, with normal cardiovascular systems whom they investigated, nearly all showed an inversion of T in one or more leads on assuming the erect position; this change was most consistent in leads 2 and 3. It made little difference whether the electrocardiogram was taken immediately on the assumption of the erect position or after standing for 12 minutes; and in 28 instances in which an electrocardiogram was taken as soon as the subject lay down the T wave immediately returned to its original height and configuration. This last observation suggests that the changes are not due to orthostatic anæmia or coronary insufficiency; moreover the T wave became higher after exercise in the erect position and lower after the administration of nitroglycerin. On the other hand they found that the inversion of T produced on standing was exaggerated at the end of full inspiration while with full expiration in the same position the inverted wave became smaller. They suggest, with good evidence, that inversion of the T wave on standing up is due to the change in the position of the heart in relation to the diaphragm and neighbouring tissues. This means that the position of the patient while electrocardiograms are being recorded is important; unless the patient is lying down inversion of T, especially in leads 2 and 3, may be found even where the cardiovascular system is normal. The routine adoption of the supine position would reduce considerably the number of cases in which inversion of T leads to confusion in diagnosis. The relationship between these electrocardiographic findings and postural hypotension—the condition in which a sudden fall of blood-pressure accompanied by loss of consciousness occurs on standing up—is worth considering. According to Stead and Ebert[2] the primary factor in this condition is a loss of the reflex vasoconstriction which normally maintains the arterial pressure when people stand up. By experiment they have shown that three patients with postural hypotension did not pool more blood in the lower part of the body on standing than normal subjects, but that pooling of the normal amount of blood caused an abnormal fall in blood-pressure. They suggest that the primary lesion lies in the sympathetic nervous system, though whether centrally or peripherally remains indefinite. On the whole they think that the lesion is likely to be in the sympathetic centres, or their efferent tracts in the central nervous system. Their results run counter to the suggestion of Maclean and Allen,[3] that postural hypotension is due to an inadequate return of venous blood to the heart It would have been of interest to know the electrocardiographic findings in Stead and Ebert's patients, even though Scherf and Weissberg found that in their cases the T wave changes and the blood-pressure were not correlated It is perhaps improbable that any correlation would be found in patients with postural hypotension, yet if a change of position of the heart can cause electrocardiographic changes in the normal subject it might well affect even more decidedly the chemistry, electrical potentials and functioning of the myocardium in patients with an autonomic disturbance

PAROXYSMAL TACHYCARDIA IN INFANTS

To count the pulse accurately in young infants is notoriously difficult This may well account for the paucity of case-reports of abnormally rapid pulse rates due to abnormal states of cardiac function Thus J P Hubbard[4] of Boston, was able to find only 19 reported cases of paroxysmal tachycardia or auricular flutter in infants less than one year old in whom the rates were established by polygraph or electrocardiographic records He reports 9 cases of his own, however, 6 of which were observed in one year, and the graphic clinical picture he draws should enable others to detect this interesting abnormality In all 9 cases the ventricular rates varied from 220 to 305, demonstrated electrocardiographically, in 7 of them the age of onset was within the first month of life, one case being noted on routine examination of a baby aged ten days on its discharge from a maternity unit Cases have in fact been reported of abnormal rates noted before birth The tachycardia may be associated with some other illness, possibly birth trauma, or may start for no obvious cause If it continues, congestive failure develops with symptoms which may first draw the attention of the parents or doctor to the fact that the baby is ill The clinical syndrome is characteristic vomiting occurs and may be severe enough to suggest pyloric stenosis, the baby becomes limp and has a dusky, greyish colour The heart is found to be beating at a rate which is often too fast to be counted and the radial pulse is as a rule imperceptible The heart enlarges rapidly, severe dyspnœa ensues with a respiratory rate which may mount to 150–160 per minute The liver becomes engorged and its edge may be felt as low as the iliac crest Œdema of dependent parts may develop The temperature usually rises and there is a leucocytosis The attack may stop spontaneously, but is likely to proceed to a fatal termination unless digitalis is given promptly Hubbard uses Digifoline, giving an initial dose of 0 05–0 1 g intramuscularly and repeating it until the desired effect is obtained One baby, weighing 9 lb, required 0 3 g of digifoline in the course of two days before the cardiac condition was controlled Once digitalisation is achieved the heart promptly returns to a normal rate and rhythm The temperature and respiratory rate also return rapidly to normal, the heart decreases in size and the liver edge shrinks back to the costal margin There is often considerable diuresis with consequent loss of weight, the colour and general condition of the child usually show a striking improvement Hubbard's electrocardiographic records show a tachycardia of supraventricular origin, in no case was there evidence of auricular flutter After effective treatment there were short recurrences in a few cases, but eventually these ceased, as far as a relatively brief period of follow-up (six months at least) showed there was no tendency for the condition to persist Attacks similar to those described might be mistaken for pneumonia or an acu infection, but complete examination should establish t rapid onset of heart failure with severe tachycardia, th response to digitalis should clinch matters

ANOTHER USEFUL SULPHONAMIDE

SULPHAMIDOTHIAZOLE (Cibazol or Ciba 3714), a nea relation of sulphapyridine, has lately been recommended for a variety of infective conditions by a group of Sw workers W Brunner and E Schläpfer[1] have used th compound in powder form in the local treatment of 10 potentially infected wounds of various types Of these 106 healed by first intention, there were no alarming inflammatory or other reactions in any instance, nor did healing appear to be retarded Necroses and hæmatomas were rarely observed in the wounds Amounts of the powder varying from 0 3 to 3 8 grammes were usually instilled, and in some cases, where there was no obviou risk of infection, a depot of the powder was established in the wound Apart from this the treatment was of the simplest surgical character and no attempts were made either to excise the wound or to secure immobilisation in the healing stages Portions of tissue excised for bacteriological examination before and immediately after the instillation of cibazol showed a pronounced falling off of positive cultures in the latter Cibazol has been given by mouth or by intramuscular or intravenous injection in obstetric and gynæcological cases by H Winzeler[2] As a prophylactic agent in normal childbirth the result were inconclusive, but in 40 patients in whom manipulative interference complicated childbirth the results suggested that, when started immediately after parturition, this form of medication was of definite benefit, the criterion of usefulness being the temperature chart In th secondary febrile complications of pregnancy, such a puerperal endometritis and mastitis, the effects wer unconvincing Winzeler observes that, in a total of 20 treated cases, doses of up to 60 g are well tolerated especially when given by mouth No harmful reaction were noted even after intramuscular and intravenou injections Laboratory analyses showed no damage t either the renal or hæmopoietic systems J Flagg an P Koenig[3] have applied cibazol locally in the form flexible pencils containing 10% of the sulphonamide f cervical endometritis In 23 cases of varied ætiolog which received regular treatment the discharge ceased improved in the majority *It is not clear from the repo whether these good effects were maintained after th* cessation of treatment, the series is too small to affor conclusive results but suggests the desirability of furth investigations Lastly A Schnieper[4] records the ben ficial effects of cibazol as an ointment, containing 5 of the active agent, in pus-coccal infections of the ski He found it especially valuable in the treatment of th commoner forms of impetigo, in 15 cases of which th eruption cleared up within 5–10 days and improvemen was obvious within 12–24 hours of starting treatment

DR PAUL FILDES, F R S, has been appointed a membe of the governing body of the Lister Institute, in plac of the late Prof William Bulloch

SIR WILLIAM WILLCOX, consulting physician to St Mary's Hospital, Paddington, died at his London home o July 8 We also regret to announce the death on July of Dr DOUGLAS STANLEY, emeritus professor of pharma cology and therapeutics in the University of Birmingham Professor Stanley was at one time editor of the *Birminghan Medical Review*, which has this week lost one of its mos stimulating writers through the death of Dr F G LAYTON on July 3

THE JIGGER FLEA

R M GORDON,
M D DUBL , SC D , F.P C.P , D.P H , D T M
ESSOR OF ENTOMOLOGY AND PARASITOLOGY AT THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE

THE jigger flea (*Tunga penetrans*) has long been known cience The first printed mention of this troublesome st is probably that of Oviedo, who in 1525 described occurrence in South America

'Besides these wormes and vermin whereof we have oken there is another little mischievous worme, which we ly number among the kinds of Fleas, this Pestilence the dians call Nigua and is much less than a Flea it pearceth e flesh of a man, and so lanceth or cutteth the same (while the meane time it can neither be seene nor taken) that om some it hath cut off their hands and from others their te, untill the remedy was found to anoint the place with le and scrape it with a rasor '

om this time onwards there are numerous references it in the literature , it was not until 1867, however, at Bonnet, working in French Guiana, wrote a full count of its appearance and life-cycle Since then umerous papers have appeared on the morphology and abits of the adult fleas, but there have been few accounts the early stages of the flea and this is the more markable since the control of the pest is dependent on knowledge of its life-history Newstead, Dutton and odd published a brief description of the eggs and larvæ 1907, but it was not until 1930 that the early stages ere fully described by Hicks

WANDERING OF THE FLEA AND ITS RAVAGES

It is only natural that so common and insistent a pest s *Tunga penetrans* should have acquired a host of local ames according to the region in which it occurs ; of hese the chigoe which is the West Indian name, and igger which is its English synonym, are the most ommon As Sir Harry Johnston (1897) has pointed out his is probably the origin of the sailor's oath, " Well, 'm jiggered

The jigger was at first confined to South America and rom there it spread to the West Coast of Africa, arriving t Ambriz in Angola, by a ship the *Thomas Mitchell*, n 1872 Its invasion of Africa appears to be accurately ssociated with this ship the crew of which were eported to have been suffering from jiggers and probably pread the infection when walking bare-foot on shore ther accounts say that the *Thomas Mitchell* contrary to regulations dumped her sand ballast on the foreshore and it was from this sand that the infection originated Whatever may have been the exact source of the infection the pest spread rapidly, downwards to the Gold Coast and inland across the continent by trade routes and by expeditions such as Stanley's expedition of 1888 which introduced the flea far into the interior (Stanley 1890) Sir Harry Johnston records its appearance in Karonga, Nyasaland in 1891 and from there it spread across East Africa appearing at Chinde on the coast of Mozambique in 1895 Once again it crossed the sea and is recorded by Blanchard in Madagascar in 1899 apparently introduced there by the tirailleurs senegalais From this date onwards it has threatened to invade the whole of Africa. The first description of its appearance in the Anglo-Egyptian Sudan is to be found in the report of the Wellcome Research Laboratories for 1906 Adam records it in the Transvaal in 1912 and its unwelcome visitation to the Seychelles in 1914 was officially reported (Addison 1915) but it was not until 1924 that Anderson noted its arrival in Kenya Having invaded two continents it was only natural for it to appear in a third and actually this ubiquitous flea has travelled from Africa to India, where according to Castellani and Chalmers (1919), it was first introduced in 1899 by the 4th Bombay Infantry Coates (1899), writing from Calcutta draws attention to the dangers of its introduction into India—a wise and necessary warning—but fortunately none of the widely varied climate of India appears to have suited the jigger and it has never become firmly established there

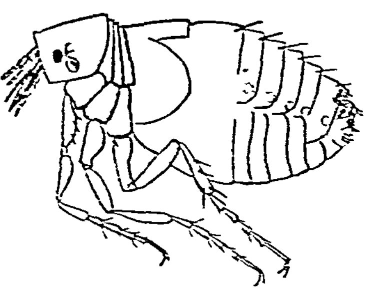

FIG 1—*Tunga penetrans* Female before entering skin (× 50)

There is a dangerous tendency among Europeans living in the tropics to regard the jigger as a trivial affliction, but experienced observers know that it may cause much suffering and loss of man-power and that " it is a pest not to be trifled with " (Patton and Evans 1929)

Charles Waterton (1825) repeats the warning of Oviedo when he says, ' There is some credit in facing a rattlesnake, killing a jaguar, or in braving the many dangers of tropical travel, but there is none in becoming the victim of a flea, though the apparently insignificant enemy may, unless its attacks be properly repelled, cause the loss of a limb, or even of life " The rôle of the jigger flea in incapacitating troops and travellers has been confirmed by numerous writers Sir Harry Johnston (1897) writes " At first it caused terrible suffering amongst our naked-foot soldiers, policemen and postmen, many of whom became lame by its bites It caused the administration to go to great expense in providing boots for all these people " Decle (1898) gives a vivid description of the havoc wrought by this insect pest ' At Fort Raymond the garrison consisted of 160 askaris (soldiers) and 70 porters , out of this number of men 72 askaris and 30 porters were absolutely unfit for service through ulcers brought on by jiggers, and 30 more men were lame At Fort Grant the proportion of invalids through jiggers was over 50% I was in charge of the Medical Department—having volunteered to help Major Owen during the War—and never in my life have I seen such awful ulcers Some of the men had the bone of their big toe protruding fleshless for more than an inch, others had quite a square inch of the bone of the heel exposed " The Official History of the War (1923) records that in the operations in the Cameroons " about 346 of the minor septic admissions were due to chiggers, some 5% of the total, but this percentage did not represent the prevalence of this pest in certain areas of the Cameroons, where its serious effects upon those native soldiers who had no experience of this minute burrowing insect or how to extract it without leaving a small sore where it burrowed, caused at one period serious military inconvenience The Northern Nigerian troops employed with the western column were crippled at one time by chiggers and were only rendered fit by the combined employment of sandals and frequent foot inspection "

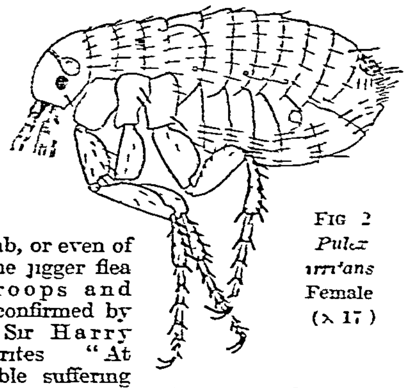

FIG 2 *Pulex irritans* Female (× 17)

LIFE-HISTORY

The adult *Tunga penetrans* (fig 1) which belongs to the family Sarcopsyllidæ in general resembles the fleas belonging to the family Pulicidæ (fig 2) which we are accustomed to see in this country but it is smaller and does not possess the same jumping powers Captured specimens can easily be identified if they are placed in a drop of pure carbolic, allowed to clear for a few hours and then examined under the microscope In the pulicidæ the head is rounded and helmet-shaped, in the sarcopsyllidæ it is angulated , in the pulicidæ the three thoracic segments are more or less rectangular in shape, whereas in the sarcopsyllidæ they are telescoped at their upper margin and tend to be triangular The life-history and habits of the male jigger flea closely resemble those of the common human flea (*Pulex irritans*) in this country, but the female furnishes a remarkable example of a free-living blood-sucker becoming for the latter part of her life a fixed parasite She jumps from the ground on to the bare foot of the person attacked, and having obtained her blood meal burrows into the skin, usually on the under surface of the toes or the junction of the nail with the skin

As Waterton (1825) remarks, "A knowing eye may always perceive when the feet of negroes are the abode of the Chigoe They dare not place their feet firmly on the ground, on account of the pain which such a position would give them, but they hobble along with their toes turned up, and by this you know that they are not suffering from tubboes (a remnant of yaws), but from the actual depredations of the Chigoes"

The female flea ceases to burrow when the last abdominal segments are almost level with the skin surface, the fertilised ova now develop with great rapidity and distend the abdomen to a relatively enormous size, so that the flea, which was originally a minute flattened creature only 1 2 mm in length, becomes within little more than a week a globular object, often 6 mm in diameter (fig 3) From now on the eggs are steadily discharged from the vagina, which protrudes from the skin, and fall on to the floor or ground one by one The process of egg-laying lasts for a week to ten days, during which time 150–200 eggs are deposited Once the parent flea has completed her function of egg production, she dies, and her shrivelled carcase is eventually sloughed out of the wound in the skin The egg is a minute oval body less than 0 5 mm in length, and from it, in three to four days, the larva emerges (fig 4), this it does by means of the so-called "egg breaker," a chitinous structure on the head with which it slits the eggshell from end to end, as though using a tin opener The larva which emerges resembles a tiny caterpillar and seeks shelter in some shaded corner, where it feeds voraciously on the organic matter found in the dust of its environment Bonnet (1867) failed to rear the larvæ except on the corpse of the parent, but Hicks (1930) has shown that such organic matter as dried blood vegetable oil and dried insect remains provide a satisfactory food-supply Unlike the larva of most other fleas, that of *Tunga penetrans* only passes through two larval stages, the pupa being formed about a fortnight after the larva has emerged from the egg In order to protect itself during this resting stage, the larva constructs a silken cocoon, which it weaves with its mouthparts from a liquid secretion emitted by the silk glands in the head, and as it weaves it mixes with the threads of silk particles of grit and rubbish from the dust, so that the cocoon, when finished, is difficult to detect Within this cocoon it casts its second larval skin and becomes a pupa (fig 5), the perfect flea emerging after a minimal period of about a week It is not known whether the jigger flea shares with the pulicidæ the remarkable power of remaining dormant in the pupa for long periods In the pulicidæ the adult flea only emerges from the cocoon when some vibration supplies the necessary stimulus, so that people entering a house which has been unoccupied for many months are often attacked by hoards of newly hatched fleas, it is probable that *Tunga penetrans* behaves similarly, since there are records of jigger infestations occurring after troops have entered long-evacuated villages

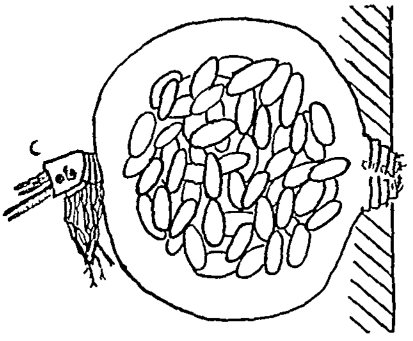

FIG 3—*Tunga penetrans* Female distended with eggs, embedded in skin

PROPHYLAXIS AND TREATMENT

The prevention of jigger infestation and the treatment of the infection when acquired are simple when once the life-history and habits of the insect are understood For this reason it is all-important that troops, before going to the tropics, should be warned about the dangers of this devastating pest and told how it may be avoided An old African school-teacher was once asked what people in his country were most liable to contract jigg He replied without hesitation, "Little children, lun and Europeans" It is only the helpless and the igno who are likely to acquire the infection in its most sere form Since the larvæ need shade and feed on the d found in the dust, rooms which are kept clean and fre exposed to sunshine do not tend to harbour th Clean, airy rooms and a clean camp unquestio reduce the risk of infection Spraying the floors with an insecticide kills not only the larvæ but also the adults An appropriate preparation can be made as follows

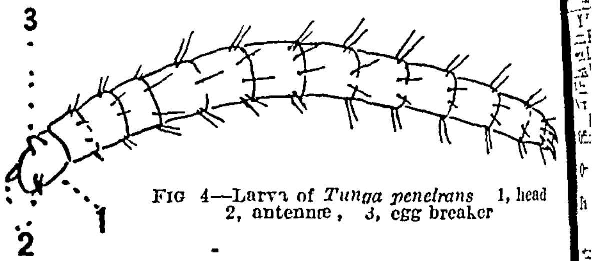

FIG 4—Larva of *Tunga penetrans* 1, head 2, antennæ, 3, egg breaker

Three parts of soft soap are thoroughly melted by heat in *15 parts of water*, and while still hot 70–100 parts of oil (petroleum, kerosene or paraffin) are added gradually, with much shaking and stirring The proper emulsification depends upon the *gradual* addition of the oil and thorough agitation The final mixture should be white and creamy, with no free oil For use dilute 1 part with 20 or even more parts of water (Waterson 1937)

As fleas go, the jigger is not a good jumper, and she seldom attacks the skin above the dorsum of the foot Hence, footwear is the most important safeguard against infection, and anyone visiting the tropics should make it a rigid rule that he does not walk about in bare feet—a maxim which, if followed will protect him not only against jiggers but against many other tropical infections In addition, it is essential that the feet should be regularly inspected in order to detect the presence of the flea in its early and comparatively harmless stage With native troops it is often impossible to supply footwear, or even when footwear is available to persuade them to make use of it, in such circumstances regular foot inspections are the chief safeguard These enable the medical officer to detect a spreader of the infection—a person whose feet harbour the "ripe" jiggers, which are discharging eggs and will spread infection throughout the camp—and also to perceive the early infections, when the jigger has only just penetrated the skin and when the eggs have not begun to develop *Tunga penetrans* parasitises other hosts than man, pigs are especially liable to attack, and these animals should be kept at a safe distance from the camp

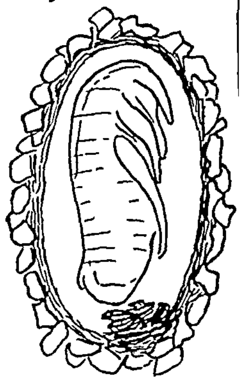

FIG 5—Pupa lying in cocoon, outer surface of which is covered with particles of sand Dark object below pupa is discarded skin of larva

Treatment consists in removal of the flea at the early stage when the only evidence of its presence is a slight itching, which may be traced to a tiny dark spot representing the point of the abdomen of the buried flea At this stage the insect can be easily and painlessly extracted with a needle The extraction of the fully developed pregnant flea, which is as large as an ordinary pea, is a much more difficult and painful matter, especially as it is usually complicated by secondary infection When there are large numbers of cases among troops it is impossible for the medical officer to attend personally to all the extractions, and he will find it more satisfactory to gather together a number of intelligent natives who have been accustomed to the technique of extraction since childhood To this skilled knowledge of the process of extraction, the medical officer must add some simple rules regarding the observance of asepsis, he must teach his first-aid squad how to clean the needles used for the extraction and the skin on which they are g to work Having done so, he will find that these can rid the sufferers of their jiggers with a skill and erity which he himself could acquire only by weeks actice

HOSPITALS AND AIR-RAIDS

ORGANISATION OF A CITY CASUALTY HOSPITAL

IT is the aim of our war-time medical services to provide th as little delay as possible, albeit in the face of new, rying and often difficult conditions, the best possible itial treatment and the fullest possible restoration to alth and efficiency of each individual casualty resses and numbers may sometimes necessitate but ust not become an excuse for lower standards Planng in advance can achieve much, but plans must be astic and susceptible of quick change Mistakes must freely admitted and experiences constantly shared hose severally responsible for the collection, transport id treatment of wounded should have a proper underanding of each other's tasks and difficulties More tensive aerial bombardment may yet await us

In these notes the organisation of a city hospital for e reception, treatment and evacuation of casualties id associated duties is briefly reviewed The notes are ised on experience gained at a London teaching spital working as a casualty clearing station and ssessed therefore of the advantages of an ample udent personnel for the provision of dressers, clerks, retcher-bearers, runners, &c The assistance which udents have given can scarcely be overstressed It fully appreciated that, with their different constitution id the prevailing shortage of civilian male personnel, her types of hospital must needs employ alternative easures The suggestions outlined, however, with cal variations, should be generally applicable to most rge city hospitals equipped for the direct admission of isualties on a large scale It is well worth considering plication to local scout organisations for the night-time rvices, in return for supper and breakfast, of squads of over Scouts to assist with such duties as stretcherarer, tally clerk (for stretchers and blankets) or nner For help as well as training the presence of St. hn Ambulance men can also be arranged As many heel-trolleys as possible should be accumulated to ghten the work of the bearers

In hospitals serving cities already bombed or liable to bombed, provision must be made for (1) reception of ses from the ambulance, (2) preliminary inspection of juries in the receiving room followed by administration A T S (unless it be decided to make a routine of ving it in the theatre when the patient is under the æsthetic), the sorting of cases into categories according severity, and the recording of particulars, (3) suscitation, (4) operation, (5) subsequent treatment,) evacuation to a "base" hospital, and (7) mortuary entification and disposal

PERSONNEL AND THEIR DUTIES

Ideally the personnel required on duty at night during aid in a hospital capable of receiving up to or over a ndred casualties should include—

1 A medical officer in charge of staff rank
2 A senior member of the surgical staff to supervise the surgical decisions of the resuscitation ward, the theatre and the surgical wards generally
3 Operating surgeons sufficient for the available tables, say from three to five, preferably men of surgical registrar standing and sometimes including members of the general or specialist surgical staff
4 A staff physician in charge of the resuscitation ward and for consultation with the surgeon in cases of wound-shock or chest or neurological injuries
5 A receiving-room officer, either a member of the specialist staff or an experienced senior house surgeon
6 Anæsthetists, of whom one should if possible be of staff and one of junior staff rank
7 A radiologist or experienced radiographer
8 House officers
9 Matron, sisters, nurses and almoners
10 Engineering and domestic staff, porters, stretcherbearers and fire-watchers

The medical officer in charge has numerous functions to perform during an air-raid He should be assisted by a responsible secretary or telephonist and a runner, the first of these at his office or night control room, the second either at the control room and kept informed as to his moves or accompanying him on his rounds He must keep an eye on the number and rate of admissions, and when the hospital's capacity from the point of view of efficient surgery is nearing saturation must make contact by telephone (when possible) with controls or through the local police with the ambulance service or with a neighbouring hospital, stating his desire to divert convoys In practice direct communication in any case with the neighboring hospital is valuable in order to maintain a friendly reciprocity and to discover how far its staff may be working under stress or able and willing to receive If other means of communication fail messages should be sent by a returning ambulance He must tour the wards frequently during the raid to see that all is well and reassure and encourage nursing staff and patients It may be necessary for him to visit other parts of the institution or to look into some reported incident or difficulty. He may have to order the evacuation of a ward which has sustained damage or had its windows blasted, or to call up extra personnel to deal with incendiary bombs, or he may have to summon the fire brigade He must keep in touch with the matron and with the hospital engineer who is one of his most valuable lieutenants and under whose direction the fire-watchers and their reliefs should usually be disposed He must see that operating surgeons and theatre and resuscitation ward staff are relieved without undue delay after an all-night session He must consult with the surgical O C on matters of policy and particularly in regard to the pressure of work and the evacuation of casualties on the following day

The surgical O C visits the resuscitation ward (which should be a separate unit but as conveniently situated as possible both for the theatre and other casualty receiving wards) as soon as it begins to fill He should there keep the personnel to a reasonable minimum to avoid congestion and the "too many cooks" tendency When the first admissions have been attended to and have begun to benefit from the rest and warmth he should make a systematic tour of inspection, dictating a statement of the injuries in each case, ordering in consultation with the physician in charge (who remains in the ward) a transfusion here, a dressing or a dose of morphine there; marking up cases for examination with the portable X-ray plant and entering against the names of the operating surgeons on a conveniently placed black board at the entry to the ward the bed-numbers of the cases selected for them in order of need and having due regard also for the skill and experience of the individual surgeons He has the same functions to perform in respect of the ward or wards to which the less severe cases are admitted and from which cases are drawn for the theatre pending the resuscitation of the more severe The graver cases may be conveniently returned after operation to the resuscitation ward to ensure continuity of treatment He may at intervals give advice in the theatre, and when admissions are few or his other tasks are done he may elect to take a table himself for a selected case or cases Operating should never, however, be considered his prime function On the morning after a raid he should help his operating colleagues and their house-surgeons with the selection of cases for immediate evacuation and may here need to be guided by the situation and bed-state as put to him by the medical officer in charge It is most important for him to establish communication with surgeons responsible for special lesions in special centres with regard to consultations on or transfer of cases of neurological, thoracic or facio-maxillary injury

The physician in charge of the resuscitation ward has a special responsibility on the spot for all the more serious cases and (with a transfusion officer or experienced resident to help him) for the transfusion of blood, plasma or other fluids or the withholding of these He directs the sister in charge of the ward in the matter of fluids to be given by mouth or rectum, the administration of oxygen, and the undressing or movement of patients—decisions of considerable moment with the badly shocked cases He should supervise the keeping of records with full notes of pulse, blood-pressure, hæmoglobin estimations, vomiting, blood-loss, &c in all grave cases, and should assist his surgical colleague with the difficult decisions as to the optimum time for operation, decisions which his closer and more continuous contacts will materially assist When the admissions are few he should take the opportunity of making detailed continuous observations on a selected case or cases with a view to increasing his own and the general body of information on the varied manifestations composing the picture of traumatic shock and to advancing treatment In this work valuable guidance may be obtained from the shock committee of the Medical Research Council His judgment should be sought in the case of thoracic wounds and cranial or other neurological injuries It has not been found necessary to arrange for separation of the sexes in the resuscitation ward , uniformity of administration and treatment and valuable economy in time and skilled personnel can thus be secured

The receiving-room officer, who should be assisted by a sister and nurse and where available by a junior house-officer or by students, and also by the almoner's clerical staff and a sufficiency of stretcher-bearers, should make only a very superficial examination of the casualties, his aim being to decide whether they should be admitted to a resuscitation or a general ward in the case of stretcher casualties, or to a general ward or rest room for discharge in the morning in the case of the walking wounded At this stage it is quite impossible to form any considered judgment of extent of wounding, operability and so on Approximately ten minutes per ambulance load of 4 stretcher cases for his inspection and decision, for the administration of A T S (if given at this stage) and for the taking of particulars, should suffice once his team is trained He may judge that a case is too bad for any of these formalities and pass it direct to the resuscitation ward , in this event it is the duty of the almoner's clerical staff to follow and secure the particulars later He should err in the direction of sending lighter cases for resuscitation rather than in that of burdening the other wards with serious cases Among admissions will be many not requiring operation—concussions, severe bruisings, fractured ribs, simple fractures and the like It has been found that about 50% of all admissions require operation Upwards of 25% of all admissions may require resuscitation A resuscitation ward in a hospital equipped for 100 or more casualties should therefore, when possible, accommodate between 20 and 30 patients and include a side-room for necessary equipment

Out of consideration for the patients and to lighten the task of the stretcher-bearers and preserve quiet and diminish traffic in wards and passages, radiography by night should be carried out with the portable apparatus Cases requiring a fuller examination will generally be in a fitter state for this on the following day

IDENTIFICATION AND OTHER MORTUARY DUTIES

Unless the mortuary is conveniently situated and commodious, separate accommodation must be set aside for cases brought in dead or dying during the night With an admission of 100 cases there may be from 10 to 20 cases dead on arrival or dying soon afterwards A most unpleasant but very important duty is that of cleaning up these pitiful victims to make them presentable for those who come to identify them later in night or in the morning, of carefully collecting making an inventory of their belongings and p them in a bag, of discovering identity cards (which commonly lacking and in addition to which the ge use of identity discs is much to be desired), and of s ing for physical marks or other evidences which assist what is sometimes a very difficult task of re tion At one teaching hospital student volunteers ha been found to carry out these duties while a kindly tactful sister and a medical officer of junior staff interview relatives The usual mortuary assista should report as early as possible on the morning af the raid to arrange the bodies which have receiv initial attention during the night, to assure the clea ness of the viewing room and to give other assista pending removal of the bodies to the public mortuary elsewhere A proper liaison should be established w the local authority to ensure the removal of bodies to t public mortuary within twenty-four hours Trestles a a supply of old stretchers should be kept in the mortua in order to free the standard stretchers for cleansing a further use in the hospital When permission can obtained, it is of real importance, for the advancement knowledge, to carry out post-mortem examinations certain types of injury Up to date various difficult and delays have tended to thwart such inquiries

EVACUATION AND RELIEFS

When casualties by night have been numerous, complete an evacuation as possible will be necessary the morrow to clear the wards for further admissio The medical officer in charge will have obtained directi from his hospital or group officer as to the destinati of casualties including those requiring transfer to spe centres A house-physician or other house officer has not been actively engaged during the night sho superintend the loading of ambulances and hand over lists and notes to the nurses allocated by the matron accompany them It will rarely be possible to start evacuation before 2 P M , by which time the night surg and other staff should have retired to rest One of most difficult things to cater for is the filling in of E M S forms and the duplication of the fuller permanent clinical notes for retention by the hospital transfer to the " base " respectively For the comfor the more serious cases in transit to the " base " m layers of blankets are necessary to serve as mattre Where money or gifts are forthcoming there can b better benefaction than a set of a dozen Sorbo mattre with washable covers to fit the standard metal stretc These must be checked and returned with the ambul conveying nurses and equipment on the return journ

Relief surgical teams, when not available from a v ing staff, should come from peripheral hospitals T should work to a rota After a raid the teams " on c should communicate with or be warned by the hospit group officer If, however, all communications broken down they should proceed to the hospital w they serve without instructions The night teams sh stop working as soon as possible after 8 A M , and reliefs be ready for action by 10 A M When arrangem for the diversion of ambulances have been satisfac it has been rare for the admissions to one hospital t so numerous that the necessary theatre work could be finished by the midday or early afternoon followi night raid As the honorary staff in the case of voluntary hospitals have many other calls on their t a rota should be arranged for night duties by the surge physicians and anæsthetists or others available least one surgeon, one physician and one anæsthe should be on duty in the hospital during a raid Th necessary since it is unfair, when they live at a dist to summon them during the course of the raid Furt more communications may break down and the approa to the hospital become difficult When, however, t live close to the hospital it should be reasonable for t to regard an alert as the indication to go on duty large city hospital in a danger zone and lacking a med superintendent should be without the services of member at least of the senior staff during the night ho

OTHER ADMINISTRATIVE POINTS

Practices and lectures should be arranged at inter for stretcher-bearers, the decontamination and ment units (male and female) and fire-watchers e long winter evenings a weekly lecture on general s concerts and debates make a useful contribution ie maintenance of a good morale and good feeling serve to bring together as one family the workers in y departments which otherwise carry on from day to almost in ignorance of each other's functions e in the institution as a unit and in its efficiency is as ortant for the successful working of a civilian war ital as it is for a battalion in the field The medical rintendent and hospital engineer must ensure that e is a sufficient provision of sandbags and buckets at strategic points and that hoses are in order and nguishers are regularly inspected

canteen, running all night and preferably situated e to the receiving room plays an important part ing a raid as a place of meeting and physical and ntal refreshment for internal staff, roof watchers tcher-bearers, ambulance drivers and sometimes for ice or firemen working in or near the hospital If rating has started in the earlier part of the night the ole theatre staff should have at least half an hour off refreshment between midnight and 3 A M

n spite of frequent damage by bombs or fire, the jority of the large hospitals in London and the other ies affected have thus far been able to carry on their rk as casualty clearing stations without serious erruption to their essential work Certain lessons ve, however, been learned The windows of all portant offices and services should be bricked up , ese should include the night operating-theatres, receiving-room, resuscitation-ward and connecting passages ne blasting of windows, apart from the dangers of oken glass, immediately cripples or altogether prevents ork owing to the claims of the blackout and the ingress f cold air in winter-time The theatre in use by night ould not be above the ground floor and wherever possible the same rule should apply to the resuscitation and ther casualty wards Reserve water-supplies and ghting should be provided for and since gas is especially able to fail, reserve heating provisions in the shape of rimus or oil stoves are also necessary

All the alternative routes of exit from wards and the ospital should be in good order and carefully studied by he medical officer in charge and should be known to isters, house-officers and stretcher-bearers Plans of vacuation from each occupied ward should be arranged nd practised

SOCIAL SECURITY IN NEW ZEALAND

A CORRESPONDENT writes · Regulations were gazetted on April 24 and the benefits came into operation on May The chemists had little information before the latter date, and even at the time of writing (May 9) innumerable points remain to be cleared up Any chemist in business in the ordinary way may contract to provide the benefits, and it is expected that most, if not all, will do so They are to be paid by the government at their own rates less 2½%, and seem well satisfied, despite the work of costing each item in a prescription It is doubtful whether modern "medicamenta vera" such as vitamins, hormones, liver preparations and sulphonamides will be available The published tariff is limited to substances appearing in the B P. 1932 and addenda 1934/40 and the B P Codex 1934 It expressly excludes "any preparation or substance (except insulin) that is prescribed by reference to any trade-mark or trade-name or by reference to a particular maker . any serum, vaccine or antitoxin, etc" But further elucidation is forecast Medical benefit is not faring well According to B M A information only 29 out of some 600 eligible doctors are undertaking the work The bulk of the 29 work in rural areas The people are apathetic—perhaps preoccupied with events in Greece and elsewhere The government remarks from time to time that the scheme is going well The Minister of Health publicly urges trade-unionists and others to use every possible means to coerce the doctors, including threats to refuse payments of bills It is said that doctors in mining districts have been offered handsome rewards to join the scheme. The B M A has appointed a committee of three to consider an alternative scheme based on "payment per service rendered", but on the whole the doctors do not seem much interested, and are mostly overworked

In England Now

A Running Commentary by Peripatetic Correspondents

YEARS and years ago, before we had all become vitamin conscious, I was trying to track down the source of the highly unsaturated oils which (we thought then) constituted the value of cod-liver oil This took me to the Biological Station at Port Erin where I fished the plaice from the station's tanks and estimated the iodine values of their food (mussels), their livers and their muscles Naturally I heard from the biologists of the station about plankton, those floating crustacea and what not which make the Manx kipper what it is or at any rate used to be—a succulent mass of pungent oiliness As naturally I thought of investigating plankton as a source of the important ingredients in cod-liver oil Clearly I was a mutt at collecting plankton for though I was under the eye of Sir William Herdman himself I rarely got enough in my nets to make an analysis worth while And I sniffed audibly when I read Sir John Graham Kerr's letter in the *Times* about the possibility of using plankton direct as human food, for I imagined that I knew a thing or two about the human effort necessary to catch 10 g of plankton and that I would prefer to leave the nekton (i e the animals that swim—isn't it a lovely word, beloveds ?) to do my work for me Rather the herring than I, I thought Obviously I was wrong, for it seems that fifty years ago Sir William Herdman fed a breakfast dish of plankton to his yachting party without much trouble and Dr. George Clarke of Woods Hole has pointed out (*Science*, 1939) that the fisherman need not sweep the sea for his quarry he can let the tidal flow bring it into his net Prof A C Hardy suggests the long, narrow, bottle-necked Scottish lochs as ideal for the purpose But is the stuff worth all this trouble ? It was, I believe, the German biological institute at Heligoland that told us that plankton was equal to the best meat in food value It contains 20% of carbohydrate, presumably glycogen, an oily fat ranging from 7 to 19% of the dry weight, with a high percentage of protein and "ash" Even if four-fifths of the catch is water it must contain many units of vitamins A and D, a good dose of calcium and iodine, and for those who like it some roughage in the form of chitin. And nourishing in fact it is for the great rorquals, born 23 ft long, reach a length of 75 ft in only two years from birth In that time they multiply their birth-weight 27 times, and all on a diet of plankton This is a testimony to the value of plankton as food—for whales But would the British public eat it ? Next year shall we all be eating a "spread," with the flavour of shrimp paste and emulating the contour of the great rorqual ? I'm game to try anything once

* * *

Seated at his table in the Home Guard headquarters, the commanding officer moved his bony index-finger slowly across a large-scale map until it came to rest on a long, narrow wood about a mile to the west of the village "You will hide yourselves in the wood," he said crisply "We will give you quarter of an hour's start, and then the rest of the platoon will make for the wood and try to capture you Your job will be to evade the attacking force by any means you can devise" Then, looking up he suddenly bawled, "Is that clear ?" All three of us sprang to attention and exclaimed "Yessir !" simultaneously, correctly divining that the question was tantamount to dismissal

Having arrived at the wood we dispersed and I saw my fellow parachutists disappear among the trees I had made up my mind on the way that I would climb a suitable tree as I felt that even a Nazi would be original enough to become a tree-dweller until nightfall After stumbling along over the rough ground for a few minutes I came to a huge beech tree in full leaf which would suit my purpose, but obviously it would be unwise to climb the tree and depend entirely on its foliage for cover I therefore decided to camouflage myself still further Slinging my rifle on a dead branch of an adjacent fir I walked among the smaller trees and broke off leafy twigs and branches with which I bedecked my uniform Even the sidepieces of my spectacles were pressed into service and supported luxuriant tufts of beech leaves While I was putting the finishing touches to my make-up I heard the sound of breaking twigs Someone was approaching It seemed too soon for the "enemy," but playing for safety I crept back to my beech Altogether I was well pleased with my appearance as I swung myself up into the bifurcation of the old tree My ascent had to be interrupted for a couple of violent sneezes, but only a professional acrobat or a tabetic could have replaced his handkerchief in his trouser pocket more deftly than I did. About 25 ft above the ground I found I could recline comfortably against the tree trunk and dispose my sprouting extremities among the main branches The sound of footsteps on the dead leaves and twigs was now accompanied by the voices of children, but soon these died away I was alone The sun shone brightly among the topmost branches but it brought little warmth The minutes passed The leaves rustled in the wind, and the tree swayed gently to and fro My khaki was dappled with the pattern of leaf shadows that waxed and waned bewilderingly as small clouds drifted across the face of the sun On one side I commanded a view of the open country beyond the wood, and in a meadow on the other side of a low wall a pair of rooks performed graceful gliding manœuvres out of sheer enjoyment of life The clock in the orphanage half a mile away jangled the quarters and then drowsily delivered itself of a litter of eleven Suddenly, as though the beech tree were their rendezvous, the air became alive with chaffinches The fledglings among them were creating a continuous uproar, flitting hither and thither The reason for this clamour was soon apparent, the parent birds could be seen coming and going with food in their beaks Many of the younger birds perched on branches only a few feet away from me, and this was eloquent testimony to the success of my camouflage The covey disappeared as suddenly as it had arrived My next visitor was a blackbird He was near enough for me to study the expression on his face, and it seemed so plainly to disapprove of the hullabaloo created by the previous tenants that I could not withhold a chuckle The blackie promptly fled with a shriek of consternation

The time wore on The clock chimed the quarters with cumulative emphasis The hum of flies continued monotonously I began to review the possible pathological effects of prolonged ischæmia over bony prominences If I were to shift my position, I reflected, I should almost certainly be spotted by one of the platoon slinking stealthily along the wall No, I decided, I mustn't spoil the show, I would remain in this attitude, reminiscent of the postencephalitic state of flexibilitas cerea Then I became aware that something unusual was happening in the wood The birds were becoming increasingly uneasy, and in a few moments the cause announced itself, there was the noise of men's voices, and as they grew louder I recognised first one and then another member of the platoon A sudden shout signalled the discovery of parachutist number 2 who had gone to earth among the roots of a fallen woodland giant "There's only the doctor now!" I heard one of them exclaim, exulting in the success of the comb-out I sniffed contemptuously at the implied assertion that it was all over, bar shouting They would have to be pretty smart to spot me, I thought, especially as the exercise was due to finish in five minutes Now I could see them moving forward, lined out to cover every yard of the wood Nearer and nearer they came until one man was right underneath me Then he stopped He beckoned to the others There was some muttering and then a loud peal of laughter which brought the rest of the platoon at the double "Aye," shouted one of them, pointing up at me, "there he is!" Aching in every limb and as stiff as a board, I slid down the tree "I thought my camouflage was fairly good," I murmured wearily, as I looked round at them "My dear Popplethwaite," replied my section leader, "the arboreal effects are perfect, but with threequarters of your handkerchief hanging from your trouser pocket nobody could have missed you, and next time, old man, don't leave your rifle pointing at the tree you're hiding in"

* * *

Last week I did a locum for an old friend in the wilds of Norfolk His practice goes into 27 parishes and he had not had a day off in the war I did between 30 and 40 miles a day, some 25 visits, and was up on 4 night can understand these practitioners envying those are called up One thing that struck me was the tion of these country folk to bombing, of which they a good deal, for they are between aerodromes and travels much further when not interrupted by no tall houses Quite a number of them sit up all n and one woman with a bad heart hadn't had her c off at night since last November—this in spite of fact that no-one has been hurt in all these villages B B C, which to the country cottage is vox dei, or at rate the highest available authority, is responsible, that talk about shelters and safety in the lower st intended for town people, has been taken literally many in the country Not fear, but English abidingness causes these clustered and nocturnal ha ings in the kitchen An element of convention comes into it too, at the back of my heart-patie mind, I'm sure, was an idea of facing her Maker, or a other catastrophe, decently apparelled The BB should correct this In the village, they should procla bombs are about as dangerous as thunder, alw provided that two or three watchers guard against the lightning of incendiaries

One contrast I bring away from this week An o couple who had lost their boy at sea, nearly home after long voyage, his ship torpedoed, picked up by one of t boats, but lived only three hours, buried at Stornaw Jimmy wouldn't come home again—for King a country Yes, the parson and the schoolmaster h called, there was bit about him and his picture in t paper, but Jimmy wouldn't come home again That fa was slowly branding itself on their minds They show me his last fo'c'sle-written, jerky letters and a thum stained one from a mate who had survived I read the while they stared into the fire Not far away was a ver old doctor with whom I spent an evening He had n relations in the war and seemed remote from the love and hates of men He smoked a churchwarden which like judge's wig gave him an air of authority "If two bo fight, it may be true to say that one is a pugnacious litt bully and the other a nice lad, but it may also be true t say that the cause of the fight is overfeeding or under feeding or incorrect feeding This war is Nature's revol against industrialism, for which man is unfitted and which is having a disastrous effect on his physique and breeding After every war there is an intense individual desire t grow things, to resume rural life I doubt if industria man can survive 500 years"

One little problem of immunity I bring away with m A woman, talking about her husband who had a habit to bronchitis and whom I had advised to shun a perso with a cold like the devil "The funny thing is t never catches a cold from me, however bad a one I have but if he goes near the grandchildren when they have colds he always gets it"

* * *

Over the imposing gateway of the municipal building in the provincial town where I am stationed then recently appeared the legend "Ministry of Food Tow Hall Restaurant," and after giving it a week or two to get going I went to lunch there taking with me a female colleague as an expert observer The place was cheer fully decorated in bright colours with posters on the wall, the tables and chairs of pleasant design and the crocker definitely non-institutional in type We queued for our "discs" at the pay desk and then queued again at the servery to obtain the food Soup 2*d*, main dish 7*d*, sweet 3*d*, with tea 1*d* or coffee 2*d* provided a large repast Even at the rush hour—just after 1 P M —then was little delay in passing the two bottle-necks, and the food was reasonably hot though not hot enough for my companion We were fortunate in having as the main dish the celebrated "Woolton Pie," a little too spiced for my palate, but I enjoyed its mixed vegetables after a slight initial prejudice because my portion of pie crust was lifted on by the fingers of the server We omitted the sweet and had coffee, which was both good and hot I would have liked a peep behind the scenes, but I had a clinic to get back to and they were at their busiest tim in the kitchen Only one or two criticisms occurred to us There were several voluntary workers in the servery which seems a pity for two separate reasons, in the first place, I had been given to understand that the whole ur was on a strictly business footing, and use of untary labour obviously plays havoc with that and re may be difficulties about having paid and unpaid kers side by side , secondly, some voluntary workers not get rid of the Lady Bountiful attitude when they dle food I ignorantly omitted to collect my spoons l forks at one stage in the queue and I was shouted in such a way that I felt the complete refugee I was o disappointed by the lavatory accommodation It too much to hope that the democratic principles volved in a communal restaurant will lead to the labels "Men" and "Women" instead of the habitual Gentlemen" and "Ladies", and in any case that is a fle But I was shocked to find that absence of soap d towels prevented the exercise of elementary hygiene—mely, the washing of the hands before meals, especially ter urination and defæcation Surely liquid soap and ssibly paper towels could be provided

Letters to the Editor

WHY THIS SHORTAGE OF NURSES?

SIR,—Ten years ago THE LANCET undertook a notable ublic service when it established a commission of iquiry into the conditions of the nursing service Its wo reports fell on stony ground and though a few rocks ave since been shifted there has been little serious ultivation The shortage of nurses continues , in some lirections it has indeed merited the epithet of "stay out" strike In a recent issue (*Lancet*, May 17, p 652) here is a note about the difficulty of the Worcestershire county council in staffing its fever and tuberculosis hospitals The various suggestions sent by that county to the Ministry of Health show how little the root of the matter is appreciated—viz the financial unattractiveness of the nursing life when regarded as a serious long-term profession It is very regrettable that such a difficulty as the non-transferability of pension rights from voluntary to statutory hospital service and vice versa should continue after years of "investigation"

Reforms happen when people really care, so one is forced to the conclusion that those who could bring them about have not cared enough In this connexion is the medical profession blameless? Are we not too ready to leave nurses to fight their battles alone? A more general coöperation both as to present needs and to the planning of future services is surely desirable The government committee of 1938/39 which was taking evidence on the nursing situation ceased working when the war started This should begin again on a combined call from the medical and nursing sides of both the voluntary and statutory hospital services

Beaconsfield ESTHER CARLING

RASPBERRY-LEAF TEA

SIR,—Professor Burn and Mr Withell are to be congratulated on their success in isolating an active substance from infusions of raspberry leaves where former investigators have failed There is a deeply rooted and widespread tradition that raspberry-leaf tea, taken during pregnancy, helps to give a painless labour Certainly in a good many cases in my own experience the subsequent labour has been easy and free from muscular spasm Somewhat shamefacedly and surreptitiously I have encouraged any expectant mothers, who felt so inclined, to drink this infusion although I have been obliged to ascribe the good results more to faith than to anything else It seems however, that the faith was reinforced by the physiological action of the active principle and this result is of the greatest interest to obstetricians

That the active substance causes relaxation and not contraction of the uterine muscle is the result which might have been expected on clinical grounds More labours are held up by spasm caused by muscular and nervous tension than are delayed by muscular weakness There is interesting work to be done in the future in a series of cases with the necessary controls It is pleasant to find a rational basis for traditional remedies, and parturient women may have cause to be grateful to Professor Burn and Mr Withell

Kensington W 8 VIOLET RUSSELL.

SAVING ON DRUGS

SIR,—Dr Pappworth deplores the neglect by hospitals and practitioners of the M R C War Memorandum No 3 It may interest him and your readers to know that after reading his paper and your leading article of Jan 4 one small hospital of 84 beds took the following action The drug committee approved a "War Pharmacopœia," prepared by its chairman, containing exclusively drugs in class A The medical committee unanimously adopted it for use in the wards and outpatient department Typed copies were distributed to all concerned, and the dispenser was instructed that class B drugs and any prescriptions not included in the war pharmacopœia are to be dispensed only when the order is signed by an honorary physician or surgeon Thus even such ordinary drugs as cascara, squill and liquid paraffin cannot be used thoughtlessly or as a routine

The amount saved is perhaps a drop in the ocean, but *necesse est minima maximorum esse initia*

G M WAUCHOPE,
Chairman of the Medical Committee

New Sussex Hospital,
Brighton

STATE MEDICAL SERVICE

SIR,—A meeting of general practitioners, mainly from the Islington area but including several doctors from adjoining boroughs, took place at the Royal Northern Hospital on June 24 Altogether 58 doctors were present A scheme for a state service was discussed at length, and a good deal of criticism was expressed of the B M A Planning Commission, because general practitioners were not represented on it in proportion to their numbers

The following resolution was passed by 35 to 4 —

> That this meeting of North London medical men, having discussed the question of a state medical service, is in favour of this , considering that it will be in the interest of the public and of the medical profession It is resolved that the success or failure of such a scheme depends on the adequate representation of the general practitioners of the country We therefore demand that the general practitioners should by free election appoint their members to form a majority on a planning board for the institution of a state medical service

A committee was elected to implement the decisions arrived at, and to link up with practitioners in other areas who hold similar views

P INWALD,
Hon Secs

Holloway Road, N 19

PEMPHIGUS NEONATORUM

SIR,—The outbreak described by S D Elliott, E H Gillespie and Eardley Holland in your issue of Feb 8 (p 169) was helpful to me in the investigation and control of an outbreak in a maternity ward in Barnsley in which ten babies were affected I was particularly interested in the typing of staphylococci described by a member of the pathological department of the Royal Berkshire Hospital, Reading, who was also good enough to type the cultures obtained from the Barnsley cases All cases which were tested from lesions of the babies were of the same type—namely, *Staphylococcus aureus* type III

Among the features common to both outbreaks was the discovery of a nurse suffering from whitlow, from which *Staph aureus* was recovered in pure culture But in the Barnsley occurrence the organism was not typable, and was of a different strain to the organisms from the pemphigus lesions, although of the same family of *Staph aureus* It would seem, therefore, that the organism was not responsible for the outbreak Prior to the advent of the technique of typing staphylococci one might have assumed that, as organisms from nurse and patients were all *Staph aureus*, the cause of the outbreak was obvious I think a negative result is worthy of report as the circumstances of the outbreak were superficially similar to the outbreak described in your issue of Feb 8, but probably entirely [illegible] nature

Other means of infection swabbing of nose and throat showed that 40% were carriers was also evidence of a cloud of origin manifesting itself in im was putting the finishing touches to my make-up I heard the sound of breaking twigs Someone was approaching It seemed too soon for the “ enemy,” but playing for safety I crept back to my beech Altogether I was well pleased with my appearance as I swung myself up into the bifurcation of the old tree My ascent had to be interrupted for a couple of violent sneezes, but only a professional acrobat or a tabetic could have replaced his handkerchief in his trouser pocket more deftly than I did About 25 ft above the ground I found I could recline comfortably against the tree trunk and dispose my sprouting extremities among the main branches The sound of footsteps on the dead leaves and twigs was now accompanied by the voices of children, but soon these died away I was alone The sun shone brightly among the topmost branches but it brought little warmth The minutes passed The leaves rustled in the wind, and the tree swayed gently to and fro My khaki was dappled with the pattern of leaf shadows that waxed and waned bewilderingly as small clouds drifted across the face of the sun On one side I commanded a view of the open country beyond the wood, and in a meadow on the other side of a low wall a pair of rooks performed graceful gliding manœuvres out of sheer enjoyment of life The clock in the orphanage half a mile away jangled the quarters and then drowsily delivered itself of a litter of eleven Suddenly, as though the beech tree were their rendezvous, the air became alive with chaffinches The fledglings among them were creating a continuous uproar, flitting hither and thither The reason for this clamour was soon apparent , the parent birds could be seen coming and going with food in their beaks Many of the younger birds perched on branches only a few feet away from me, and this was eloquent testimony to the success of my camouflage The covey disappeared as suddenly as it had arrived My next visitor was a blackbird He was near enough for me to study the expression on his face, and it seemed so plainly to disapprove of the hullabaloo created by the previous tenants that I could not withhold a chuckle The blackie promptly fled with a shriek of consternation

The time wore on The clock chimed the quarters with cumulative emphasis The hum of flies continued monotonously I began to review the possible pathological effects of prolonged ischæmia over bony prominences If I were to shift my position, I reflected, I should almost certainly be spotted by one of the platoon slinking stealthily along the wall No, I decided, I mustn't spoil the show , I would remain in this attitude, reminiscent of the postencephalitic state of flexibilitas cerea Then I became aware that something unusual was happening in the wood The birds were becoming increasingly uneasy, and in a few moments the cause announced itself , there was the noise of men's voices, and as they grew louder I recognised first one and then another member of the platoon A sudden shout signalled the discovery of parachutist number 2 who had gone to earth among the roots of a fallen woodland giant “ There's only the doctor now ! ” I heard one of them exclaim, exulting in the success of the comb-out I sniffed contemptuously at the implied assertion that it was all over, bar shouting They would have to be pretty smart to spot me, I thought, especially as the exercise was due to finish in five minutes Now I could see them moving forward, lined out to cover every yard of the wood Nearer and nearer they came until one man was right underneath me Then he stopped He beckoned to the others There was some muttering and then a loud peal of laughter which brought the rest of the platoon at the double “ Aye,” shouted one of them, pointing up at me, “ there he is ! ” Aching in every limb and as stiff as a board, I slid down the tree “ I thought my camouflage was fairly good,” I murmured wearily, as I looked round at them “ My dear Popplethwaite,” replied my section leader, “ the arboreal effects are perfect, but with threequarters of your handkerchief hanging from your trouser pocket nobody could have missed you , and next time, old man, don't leave your rifle pointing at the tree you're hiding in ”

Last week I did a locum for an old friend in the wilds of Norfolk His practice goes into 27 parishes and he had not had a day off in the war I did between 30 and 40 miles a day, some 25 visits, and was up on 4 nights
can understand these practitioners envying those v
are called up One thing that struck me was the re
tion of these country folk to bombing, of which they h
a good deal, for they are between aerodromes and n
travels much further when not interrupted by rows
tall houses Quite a number of them sit up all nig
and one woman with a bad heart hadn't had her clot
off at night since last November—this in spite of
fact that no-one has been hurt in all these villages T
B B C , which to the country cottage is vox dei, or at a
rate the highest available authority, is responsible ,
that talk about shelters and safety in the lower stor
intended for town people, has been taken literally
many in the country Not fear, but English l
abidingness causes these clustered and nocturnal hud
ings in the kitchen An element of conventional
comes into it too , at the back of my heart-patie
mind, I'm sure, was an idea of facing her Maker, or a
other catastrophe, decently apparelled The B B
should correct this In the village, they should procla
bombs are about as dangerous as thunder, alw
provided that two or three watchers guard against
lightning of incendiaries

One contrast I bring away from this week An
couple who had lost their boy at sea, nearly home afte
long voyage, his ship torpedoed, picked up by one of
boats, but lived only three hours, buried at Stornaw
Jimmy wouldn't come home again—for King a
country Yes, the parson and the schoolmaster h
called, there was bit about him and his picture in
paper, but Jimmy wouldn't come home again That fa
was slowly branding itself on their minds They show
me his last fo'c'sle-written, jerky letters and a thum
stained one from a mate who had survived I read th
while they stared into the fire Not far away was a ve
old doctor with whom I spent an evening He had
relations in the war and seemed remote from the love a
hates of men He smoked a churchwarden which lik
judge's wig gave him an air of authority “ If two bo
fight, it may be true to say that one is a pugnacious lit
bully and the other a nice lad, but it may also be true
say that the cause of the fight is overfeeding or und
feeding or incorrect feeding This war is Nature's rev
against industrialism, for which man is unfitted and whi
is having a disastrous effect on his physique and breedin
After every war there is an intense individual desire
grow things, to resume rural life I doubt if industr
man can survive 500 years ”

One little problem of immunity I bring away with m
A woman, talking about her husband who had a liabili
to bronchitis and whom I had advised to shun a pers
with a cold like the devil “ The funny thing is
never catches a cold from me, however bad a one I hav
but if he goes near the grandchildren when they have col
he always gets it ”

* * *

Over the imposing gateway of the municipal buildin
in the provincial town where I am stationed the
recently appeared the legend “ Ministry of Food Tow
Hall Restaurant,” and after giving it a week or two
get going I went to lunch there taking with me a fema
colleague as an expert observer The place was chee
fully decorated in bright colours with posters on the wall
the tables and chairs of pleasant design and the crocker
definitely non-institutional in type We queued for ou
“ discs ” at the pay desk and then queued again at th
servery to obtain the food Soup 2*d* , main dish 7*d*
sweet 3*d* , with tea 1*d* or coffee 2*d* provided a larg
repast Even at the rush hour—just after 1 P M —ther
was little delay in passing the two bottle-necks, and th
food was reasonably hot though not hot enough for m
companion We were fortunate in having as the mai
dish the celebrated “ Woolton Pie,” a little too spiced fo
my palate, but I enjoyed its mixed vegetables after
slight initial prejudice because my portion of pie-crus
was lifted on by the fingers of the server We omitte
the sweet and had coffee, which was both good and hot
I would have liked a peep behind the scenes, but I had
clinic to get back to and they were at their busiest tim
in the kitchen Only one or two criticisms occurred to
us There were several voluntary workers in the servery
which seems a pity for two separate reasons , in the first
place, I had been given to understand that the whole

air was on a strictly business footing, and use of luntary labour obviously plays havoc with that and re may be difficulties about having paid and unpaid rkers side by side , secondly, some voluntary workers nnot get rid of the Lady Bountiful attitude when they ndle food I ignorantly omitted to collect my spoons d forks at one stage in the queue and I was shouted in such a way that I felt the complete refugee I was o disappointed by the lavatory accommodation It too much to hope that the democratic principles volved in a communal restaurant will lead to the labels “ Men ” and “ Women ” instead of the habitual Gentlemen ” and “ Ladies ” , and in any case that is a fle But I was shocked to find that absence of soap d towels prevented the exercise of elementary hygiene—mely, the washing of the hands before meals, especially ter urination and defæcation Surely liquid soap and ssibly paper towels could be provided

Letters to the Editor

WHY THIS SHORTAGE OF NURSES ?

SIR,—Ten years ago THE LANCET undertook a notable iblic service when it established a commission of quiry into the conditions of the nursing service Its vo reports fell on stony ground and though a few rocks ive since been shifted there has been little serious ltivation The shortage of nurses continues , in some rections it has indeed merited the epithet of “ stay it ” strike In a recent issue (*Lancet*, May 17, p 652) iere is a note about the difficulty of the Worcestershire ounty council in staffing its fever and tuberculosis ospitals The various suggestions sent by that county the Ministry of Health show how little the root of the iatter is appreciated—viz the financial unattractiveess of the nursing life when regarded as a serious long-erm profession It is very regrettable that such a ifficulty as the non-transferability of pension rights from oluntary to statutory hospital service and vice versa hould continue after years of “ investigation ”

Reforms happen when people really care, so one is orced to the conclusion that those who could bring them bout have not cared enough In this connexion is the iedical profession blameless ? Are we not too ready to eave nurses to fight their battles alone ? A more eneral coöperation both as to present needs and to the lanning of future services is surely desirable The overnment committee of 1938/39 which was taking vidence on the nursing situation ceased working when he war started This should begin again on a combined all from the medical and nursing sides of both the oluntary and statutory hospital services

Beaconsfield ESTHER CARLING

RASPBERRY-LEAF TEA

SIR,—Professor Burn and Mr Withell are to be ongratulated on their success in isolating an active ubstance from infusions of raspberry leaves where ormer investigators have failed There is a deeply ooted and widespread tradition that raspberry-leaf tea, aken during pregnancy, helps to give a painless labour ertainly in a good many cases in my own experience the ubsequent labour has been easy and free from muscular pasm Somewhat shamefacedly and surreptitiously I ave encouraged any expectant mothers, who felt so nclined to drink this infusion although I have been bliged to ascribe the good results more to faith than to nything else It seems however, that the faith was einforced by the physiological action of the active rinciple and this result is of the greatest interest to bstetricians

That the active substance causes relaxation and not ontraction of the uterine muscle is the result which ight have been expected on clinical grounds More abours are held up by spasm caused by muscular and ervous tension than are delayed by muscular weakness There is interesting work to be done in the future in a eries of cases with the necessary controls It is pleasant o find a rational basis for traditional remedies, and arturient women may have cause to be grateful to Professor Burn and Mr Withell

Kensington, W 8 VIOLET RUSSELL.

SAVING ON DRUGS

SIR,—Dr Pappworth deplores the neglect by hospitals and practitioners of the M R C War Memorandum No 3 It may interest him and your readers to know that after reading his paper and your leading article of Jan 4 one small hospital of 84 beds took the following action The drug committee approved a “ War Pharmacopœia ” prepared by its chairman, containing exclusively drugs in class A The medical committee unanimously adopted it for use in the wards and outpatient department Typed copies were distributed to all concerned and the dispenser was instructed that class B drugs and any prescriptions not included in the war pharmacopœia are to be dispensed only when the order is signed by an honorary physician or surgeon Thus even such ordinary drugs as cascara, squill and liquid paraffin cannot be used thoughtlessly or as a routine

The amount saved is perhaps a drop in the ocean, but *necesse est minima maximorum esse initia*

G M WAUCHOPE,
Chairman of the Medical Committee

New Sussex Hospital
Brighton

STATE MEDICAL SERVICE

SIR —A meeting of general practitioners, mainly from the Islington area but including several doctors from adjoining boroughs, took place at the Royal Northern Hospital on June 24 Altogether 58 doctors were present A scheme for a state service was discussed at length and a good deal of criticism was expressed of the B M.A Planning Commission, because general practitioners were not represented on it in proportion to their numbers

The following resolution was passed by 35 to 4 —

> That this meeting of North London medical men, having discussed the question of a state medical service, is in favour of this , considering that it will be in the interest of the public and of the medical profession It is resolved that the success or failure of such a scheme depends on the adequate representation of the general practitioners of the country We therefore demand that the general practitioners should by free election appoint their members to form a majority on a planning board for the institution of a state medical service

A committee was elected to implement the decisions arrived at, and to link up with practitioners in other areas who hold similar views

B HYNES,
P INWALD,

Holloway Road N 19

PEMPHIGUS NEONATORUM

SIR,—The outbreak described by S D Elliott, E H Gillespie and Eardley Holland in your issue of Feb 8 (p 169) was helpful to me in the investigation and control of an outbreak in a maternity ward in Barnsley in which ten babies were affected I was particularly interested in the typing of staphylococci described by a member of the pathological department of the Royal Berkshire Hospital, Reading, who was also good enough to type the cultures obtained from the Barnsley cases All cases which were tested from lesions of the babies were of the same type—namely, *Staphylococcus aureus* type III

Among the features common to both outbreaks was the discovery of a nurse suffering from whitlow, from which *Staph aureus* was recovered in pure culture. But in the Barnsley occurrence the organism was not typable, and was of a different strain to the organisms from the pemphigus lesions, although of the same family of *Staph aureus* It would seem, therefore, that the organism was not responsible for the outbreak Prior to the advent of the technique of typing staphylococci one might have assumed that as organisms from nurse and patients were all *Staph aureus*, the cause of the outbreak was obvious I think a negative result is worthy of report as the circumstances of the outbreak were superficially similar to the outbreak described in your issue of Feb 8, but probably of an entirely different nature

Other means of infection coexisted Extensive swabbing of nose and throat of all staff and patients showed that 40% were carriers of *Staph aureus* There was also evidence of a cloud of infection of *Staph aureus* origin manifesting itself in impetigo sinusitis and other minor infections among the general public I was unable to get these organisms typed so that precise proof of the outbreak is lacking Once we were assured by bacteriologists of the validity of typing of staphylococci it would be of public health value, in investigating the many infections (apparently growing both in number and in epidemic importance) caused by the staphylococcus, for wider facilities of typing to be available Facilities for typing streptococci are general, but it was only after unsuccessful requests to a large number of laboratories that I was able to get the cultures of *Staph aureus* typed

J L BURN,
Barnsley Medical Officer of Health

THE MEDICAL DIRECTORY

SIR,—To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession Should the schedule have been lost or mislaid we will gladly forward a duplicate upon request The full names of the doctor should be sent for identification

104, Gloucester Place, W 1 J & A CHURCHILL LTD

Parliament

War-time Agriculture

IN the debate on agriculture in the upper House on July 1, noble lords eloquently defended the farmer's livestock Lord TEVIOT said that if the farmer was to go on producing food he must keep the land in good heart, and he should be allowed to keep some of his crops to feed the pigs and poultry who maintained its fertility Too much artificial fertilisers "doped" the land

Lord DAWSON said that milk was all his song and made his plea for the dairy herds Unfortunately, he said, increasing consumption of milk existed side by side with decreasing production Last February the consumption of milk increased by five million gallons, and the consumption of people who had prior needs reached ten million gallons per month But production had been falling since 1939 and was still falling On official evidence the provision of a pint of milk daily for children under 16, and half a pint for adults, would in the winter months exceed our total milk production by half During 1939–40 Germany had increased her production of liquid milk Lord Dawson urged that, after vegetables, potatoes and leguminous foods the dairy herd should have the next claim on home-grown food Although we were not justified in spoiling the land to feed the country, we were justified in straining the land, if such temporary strain would provide essential nourishment A reduction of milk consumption in the coming winter would entail risks The meat ration could be curtailed within reason and even our share of that essential food cheese could be curtailed, so long as the milk-supply was not tampered with, for it was the keystone of the nutrition problem Milk was as important as munitions, for with the rationing of foods it contributed more to the maintenance of the efficiency of our adult working population than anything else This was doubly true of sedentary workers, who needed lighter foods In many people stress and anxiety produced digestive disorders For them milk was also important They carried on, but unless they were carefully fed their ailments would become illness, and illness meant incapacity and a consequent weakening in the war effort If necessary, enough powdered milk should be introduced to carry us through the coming winter Lord Dawson hoped that every effort would be made to avoid the rationing of milk

LORD ADDISON agreed that it might be necessary in this crisis to capitalise the dormant fertility of the land, while Lord BALFOUR of BURLEIGH stressed the need for a synthesis between the often conflicting claims of industry and agriculture He suggested that nutrition might provide a good starting-point for post-war discussions

The Duke of NORFOLK, parliamentary secretary to the Ministry of Agriculture, said that the Government wished to raise the food production from our land to the maximum, and to ensure foodstuffs were produced of the kind and in the quantities we needed The Government was anxious to keep up the milk-supply, and he could assure Lord Dawson that in the culling of dairy herds no cow should be killed that was not diseased or unthrifty The total was not expected to exceed 5%

QUESTION TIME

Social Reconstruction Survey

In answer to a question Mr ARTHUR GREENWOOD, minister without portfolio, stated that the committee of the Social Reconstruction Survey consists of members appointed by the committee of Nuffield College as follows Mr G D H Col (chairman), The Master of Balliol, The Principal of Lady Margaret Hall, Prof A G B Fisher, Prof D H Macgregor, Prof A L Bowley, Sc D, Mr R C K Ensor Miss A Headlam-Morley, and Mr C H Wilson Th committee have coopted Mr C S Orwin, D Litt, Mis Margery Perham, Mr G Montagu Harris, and Pro Patrick Abercrombie, F R I B A The terms of reference o the survey are, briefly, to inquire into the redistribution o industry and population brought about by the war and th extent to which this redistribution is likely to persist in th post war period, into the effects of war conditions on th working of public social services (other than the hospita service), into the changes in conditions of living due t evacuation and similar measures taken to meet the wa situation, and into the bearing of all these factors on th general problem of national reorganisation after the war I addition to the chairman, the senior staff of the central offic of the survey consists of five full time research workers an one part time research worker There is also a clerical sta of five The survey employs, in different areas of the country 21 chief local investigators, two of whom are members of th senior staff of the survey To assist them chief local investigators have appointed a number of assistant investigator The work of all local investigators, except those employe on the central staff of the survey, is part time, and most loca investigators are giving their services free The bulk of th expenses of the survey during the current financial year will b borne by the independent resources of Nuffield College, bu the Government have undertaken to meet a grant not exceeding £5000, to be borne on the Treasury Vote, towards the expenses of the survey in that year

New Prison Dietary Scale

Mr W THORNE asked the Home Secretary if he could giv any information in connexion with the Dartmoor convic trouble, how many of the prisoners were injured, an whether he would have circulated the prison daily dietary —Mr O PEAKE, under secretary to the Home Office, replied Disturbances which took place not at Dartmoor but at Parkhurst Prison on June 3, arose out of complaints about a mea

WEEKLY RATION PER MAN

	oz		oz
Bread	140	Rice or Barley	7
Meat, fresh or preserved	12	Flour	14
Bacon	4	Dried fruit	4
Potatoes	112	Margarine	8
Jam or syrup or treacle	2	Fish, salt or fresh	20
Fresh vegetables	24	*Tea*	1
Root vegetables	14	Cocoa, Admiralty	5
Dried vegetables *	9	Cheese	1
Sugar	8	Milk	pts 2
Oatmeal	21		

* Split peas, beans or marrowfat peas

MEALS FOR A DAY BASED ON RATION SCALE

Breakfast

	oz		p
Bread	8	Porridge (*a*)	1
Margarine	½	Tea (*b*)	1

(*a*) 3 oz oatmeal, 2–4 oz milk as procurable
(*b*) ¼ oz tea, 1½ oz milk, no sugar

Dinner

	oz		o
Bread	2	Rice or barley	1
Potatoes	16	Dried vegetables	
Meat (*c*)	4	Flour	
Root vegetables	4	Cabbage	6

(*c*) Boil the beef and cut up in thin slices, issue in bottom tins Clean and cook vegetables With rice or barley add dried vegetables, season and thicken with flour, also in bottom tins Cabbag and potatoes in top tins

Supper

Bread	10 oz	Cocoa (*d*)	1 p
Margarine	½ ,,	Cheese (*e*)	1 o

(*d*) ¾ oz cocoa 1½ oz milk, no sugar
(*e*) Once a week

Each prisoner will be issued with 1 oz of sugar a day with th supper meal hich the convicts refused to eat They were given another eal instead, but some of them refused to go to their work or o return to their cells A few had to be removed with the elp of prison officers brought from the neighbouring prison of amp Hill No one was hurt These disturbances had othing to do with the new dietary scale which the Minister as approved as an experimental measure for three months he scales are to be reviewed shortly, though it is unlikely that will be possible to introduce any fundamental changes, since he scale is based on the rationing scheme applicable to the eneral public

National Health Insurance

Mr Rhys Davies asked the Minister of Health whether, in rder to avoid unfair competition among approved societies, e would insert in the new Health Insurance Bill, already romised, a provision whereby a legal contract of membership f the society should not be valid prior to the entry into nsurable employment of the applicant —Mr E Brown eplied As employed persons become entitled to, and may require, medical benefit as soon as they enter insurable employment, I think that the amendment suggested would operate to their disadvantage because under the arrangements envisaged by him delay in securing medical benefit would be inevitable

School Milk at Morecambe

Mr Gordon MacDonald asked the President of the Board of Education whether a satisfactory plan for the provision of milk in schools had been adopted in Morecambe, and what steps he was taking to ensure the provision of an adequate supply of milk to the schools in that borough — Mr Herwald Ramsbotham replied The local education authority resolved to adopt the milk-in-schools scheme as long ago as Nov 18, 1940, but they have not yet implemented this decision Difficulties in obtaining a supply of milk may have accounted for the delay during the early part of this year The Milk Marketing Board at the request of the Board of Education are giving all possible assistance I am informed that the authority have taken no steps to secure milk from one supplier who is known to have an adequate supply of satisfactory quality, and that an alternative but insufficient supply is also available No contract has been placed I view the authority's delay with very grave concern and I am pursuing the matter with them

Public Health

Tuberculosis Death Rate Rising

Figures published by the Registrar-General for Scotland show that under war conditions there has been some rise in the deaths due to tuberculosis (*Lancet*, June 21st, 1941, p 809) Corresponding figures for England and Wales have unfortunately been lacking, the 1938 tables of the Registrar-General being still the latest available, though Dr Percy Stocks in his review of war-time mortality (*Lancet*, 1940, 1, 725) showed that the deaths from tuberculosis in London during 1939–40 were in excess of the number expected Recently, however, some broad data were provided by the Minister of Health in reply to a question in the House of Commons, and, using the Registrar-General's returns for earlier years, it is possible to study the trend of mortality over the pre-war years and up to the end of 1940 The figures below set out the position as shown by the absolute numbers of deaths since 1934 Except for an occasional break in the first half of influenza years (e g 1937) the well-known decline in tuberculosis mortality was continuing satisfactorily The war has clearly produced a set-back In the last quarter of 1939 there was a slight rise in the number of deaths of males, though not of females In 1940 there was a distinct rise for both sexes throughout the year Compared with the immediate pre-war year 1938, deaths of males increased by somewhat over a thousand, or by 8%, deaths of females by somewhat under a thousand, or by 7% Roughly, we have slipped back 4 or 5 years This relative rise has, however, been less than in Scotland where the male and female deaths in 1940 were 18 and 15% respectively in excess of the 1938 figures, but without knowledge of the population at risk—and vast changes have, of course, taken place in its distribution—it would be unwise to stress the difference

From the Annual Reports

ST MARYLEBONE AND HACKNEY

Dr H A Bulman, in the west of London and Dr G H Dart in the north-east are faced with differing problems, and these are independent of locality, efficiency of health administration, or natural causes of variations in health Hackney (205 100) has nearly twice the population of Marylebone (104,173), its birth-rate in 1939 was 13 1 and death-rate 11 8, against the western borough's 9 1 and 12 6 The infantile mortality of Hackney was 40 9, that of St Marylebone 60 6 Among legitimates the rates were 39 3 and 48 5, and amongst illegitimates 82 5 and 161 respectively It must be remembered that Hackney is one of the London boroughs which has a low illegitimacy rate (3 5% in 1939) whereas St Marylebone (10 4%) has one of the highest That the mortality of illegitimate infants in Marylebone should be nearly double what it is in Hackney can be explained by social factors, explained, not excused The death-rates given, 11 8 and 13 respectively, are corrected by the comparability factor and therefore suggest that the people of St Marylebone are either less healthy or shorter-lived than those of Hackney, but the comparability factors are old and the movement of populations owing to war conditions renders them obsolete Tuberculosis notifications were 213 pulmonary and 34 non-pulmonary in Hackney and 111 pulmonary and 15 non-pulmonary St Marylebone The deaths were 109 and 15 in the former and 57 and 5 in the latter The higher non-pulmonary incidence in Hackney is explained by the higher proportion of children in the population Cancer mortality was distinctly higher in Hackney than in St Marylebone (344 deaths again 139) and so was mortality from diabetes (42 deaths against 14), but that from cerebral hæmorrhage was less (56 deaths against 54) This might mean that the people of Hackney are later in seeking treatment for cancer than are those of St Marylebone and less persistent in the treatment of diabetes

ILFORD

Dr A H G Burton's report of an unusually healthy year in a typical working-class outer-ring borough gives a picture of the best health conditions which could be expected with the amenities, knowledge and administrative capacity and energy available at the outbreak of the present war Within living memory Ilford was a village, it is now a section of London with 169,800 inhabitants The rapidity of its growth can be gauged by the fact that its population has doubled since the census of 1921, this increase is mainly by immigration, for its birth-rate in the past five years has averaged about 14 and its death-rate 9 In 1939 infantile mortality was 33 9 and maternal mortality 1 75 The latter is a low record, attained by the reduction of fatal infection , in 2307 births there was only one death from puerperal fever Prevention of serious puerperal infections had got to a very satisfactory state by 1937 and then the introduction of the sulphonamides gave us a powerful remedy to combat failures of prevention Of the 1450 deaths which occurred in Ilford in 1939, more than half (763) were of people over sixty-five , 31 were aged 1–15, and 47 aged 15–25 The 78 deaths of these immature people were made up as follows 13 from violence and 2 from suicide , 13 from pulmonary tuberculosis (12 in people over fifteen) , 5 from other tuberculosis , 7 from heart disease (all over fifteen) , 3 from appendicitis , 4 from acute endemic infections , 7 from acute respiratory infections, and the remaining 24 from various causes

There are approximately 42,900 inhabited houses in Ilford of which 16,312 were inspected in 1939 , bug-infestation was found in 49 There might be a few more infested houses which were not inspected, but the number would be small Other nuisances were detected in 1167, or roughly in 1 house of every 15 inspected The distribution of nuisances in houses not inspected naturally varies greatly with the energy of the sanitary inspector and his staff, but also with the nature of the property and the habits of the people To abate the nuisances detected 836 informal notices were served resulting in 707 abatements, and 312 statutory notices resulting in 253 abatements Of the statutory notices 258 were to provide dustbins

Infectious Disease in England and Wales

WEEK ENDED JUNE 28

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 840 , whooping-cough, 5437 , diphtheria, 909 , paratyphoid, 74 , typhoid, 37* , measles (excluding rubella), 8820 , pneumonia (primary or influenzal), 666 , puerperal pyrexia, 121 , cerebrospinal fever, 192 , poliomyelitis, 3 , polio-encephalitis, 0 , encephalitis lethargica, 5 , dysentery, 78 , ophthalmia neonatorum, 82 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on June 25 was 1526 , including scarlet fever, 168 , diphtheria, 301 , measles, 238 , whooping cough, 469 , enteritis, 18 , chicken pox, 62 , erysipelas, 30 , mumps, 6 poliomyelitis, 1 , dysentery, 5 , cerebrospinal fever, 40 , puerperal sepsis, 8 , enteric fevers, 11 , german measles, 8 , encephalitis lethargica, 1 , other diseases (non infectious) 67 , not yet diagnosed, 93

Deaths —In 126 great towns there was 1 (0) death from scarlet fever, 4 (0) from enteric fever,* 22 (2) from whooping-cough, 9 (0) from measles, 18 (0) from diphtheria, 26 (2) from diarrhœa and enteritis under 2 years, and 5 (0) from influenza The figures in parentheses are those for London itself

Blackpool, Manchester Birmingham and Newport (Mon) each reported a fatal case of enteric fever There were 4 deaths from whooping cough at Liverpool

The number of stillbirths notified during the week was 194 (corresponding to a rate of 41 per thousand total births), including 13 in London

---

* In Weekly Return No 26, for the first time ever, paratyphoid and typhoid are listed separately in table 4 (Notification of Infectious Diseases) In table 2 however (Deaths) they are still pooled under a common heading which we have hitherto rendered as Enteric Fever

BEFORE the days of the sulphanilamide compounds quinine had a wide following in the treatment of respiratory infections, and in the minor ones it still has In the last few years it has been demonstrated that many infections are accompanied by an increased utilisation of vitamin C Messrs ORGANON LABORATORIES have now introduced a compound of quinine and ascorbic acid, Orgaknine, which they suggest should be tried in the pneumonias, influenza and colds when specific bactericidal therapy is withheld or has failed Orgaknine is made up in ampoules for intramuscular injection and in tablets for administration by mouth

Obituary

GEORGE FREDERIC STILL

K C V O , M D CAMB , LL D EDIN , F R C P

Sir Frederic Still, whose unexpected death wa announced last week, was born in Holloway, in Februar 1868, the son of George Still, surveyor of customs H had his schooling at Merchant Taylors , thence to Caiu College, Cambridge, where he took a first in the classica tripos and was Winchester prizeman In 1893 he qualified from Guy's Hospital, where as house-physician he came into the sphere of influence of James Goodhart, to whose teaching and example he owed his leaning to the study of disease in children From Guy's he went to the Hospital for Sick Children, to which institution he remained devotedly attached during all his active life There in various offices, beginning as house-physician, he worked happily for nearer forty than thirty years Other hospital appointments he held—when King's College Hospital opened a children's department Still was appointed physician in charge of i and of the academic chair created in 1906—and i time he had a great success as a consulting physician i the diseases of children, but no other work lay so nea his heart as that at Great Ormond Street

from a portrait by Mr Gerald Kelly R A

His scientific reputation preceded his professiona success, for quite early in his career at Ormond Street h did two pieces of work which made his name well known one established the entity of a chronic rheumatoi arthritis peculiar to childhood (" Still's disease "), th other identified the organism responsible for the affectio described many years before by Gee and Barlow a posterior basic meningitis Gee had no great influenc on Still—he had left Ormond Street before Still wen there—but Barlow became the loved and admire inspiration of Still's career With Goodhart he collaborated in the later editions of that physician's successfu textbook on children's diseases, and then he produce several further editions of the work unassisted H published articles, papers and lectures, nearly all on th more strictly clinical aspects of disease , many of thes have permanent value, for he was an acute and accurat observer His industry was astonishing to his younge contemporaries , but he had little to distract him, fo unlike most men he had no wish for the relaxation o social gatherings or sport, and the time which he might have spent on these he devoted solely to subjects connected with medicine Indeed it was with a somewhat amused surprise that in later life his friends learnt that he had become an ardent, though, as he often said, an extremely inefficient dry-fly fisherman, and later still enjoyed and added to the social amenities of the College Club

The passage of years gave him an almost unique position as a children's consulting physician, and at one period it was difficult to find a child of well-to-do and anxious parents who at some time had not been taken to see Still The International Pædiatric Congress which met in London in 1933, over which he presided, at once set the seal on his reputation and revealed even to his own profession the width of his learning, the geniality of his address and his fame among our foreign visitors For twenty years Still was the indefatigable chairman of the National Association for Prevention of Infant Mortality and when he retired in 1937 he received the K C V O It would be idle to enumerate the medical honours which fell to his lot, and all the varied responsibilities which he cheerfully assumed in public and private work He took his full share of both and relished both Suffice it that he had of later years ripened into a wider and mellower intellectual life than had in his earlier seemed probable At Cambridge he had been a notable classical scholar and the love of the classics returned to him with reasing power His enthusiasm for good literature ver failed, and he was quick to recognise and generous praise sound writing

In his early years Still, whether because of his sole votion to the work on which he happened to be gaged, or because of an innate reticence which made n outwardly irresponsive and unsympathetic, was not easy person to become intimate with His fellow-ikers admired his industry, his talents, his learning, clinical acumen, but recognised with difficulty the man being in the accomplished physician This pect entirely changed as one grew into a closer know-lge of the man, and in later intercourse nobody could more eager to get into sympathetic touch with his ends, and few could be more delightful or more urteous in conversation or genial controversy For ill held his opinions firmly, and though even an timate might never know, nor ever inquire, his political inings he would not be surprised to learn that these had arcely altered from youth up It was part of his charm a friend that you could rely implicitly on his steadfast-ss and unchanging quality

JAMES HILL WILLIAMSON LAING

M A, B SC ST AND, M B EDIN

Dr Laing, who died at Blairgowrie on June 26 in his 0th year, was for many years medical editor to the xford University Press Physician, man of letters, otanist, art critic, and not least as friend and corre-pondent, Laing had endeared himself to a large circle by s personality and by the merit of scholarship, seldom ore lightly assumed Born at Tayport an early interest biology led him to forsake the mercantile tradition and e took a science degree at St Andrews and qualified in edicine at Edinburgh University with first-class honours 1889 He was a house officer in the Royal Infirmary, ssisting the professors of clinical medicine Grainger tewart then urged him to specialise, but deferring to s mother's wishes he settled down as a general practi-ioner in Dundee, devoting his scanty leisure, often uring busy rounds in carriage or car, to the study of ooks, particularly on painters Publishers and authors egan to receive letters in which, very gently, errors were ointed out and suggestions made which, they realised, ould only come from a man of rare attainments Thus ere laid the foundations of many friendships, among hem one with Sir Algernon Methuen, for whom Laing as to edit a series of books on art Never robust his ealth proved unequal to the strain of practice and after he last war he moved to London where, after valued ervice in the LANCET Office in preparing articles for ublication, he became editor of Oxford Medical Books Iany a contributor to that series will remember his elpful criticism, his unerring eye for verbal errors, and is flair for indexing Latterly his health compelled im to winter abroad but to the last he maintained his onnexion with the University Press One of his associ-tes there writes of him "His declining years were roubled with increasing ill health, and a succession of evere surgical operations obliged him, some years efore his final illness, to relinquish almost every form f work, but Laing remained until the last keenly inter-sted in the progress of medical science, and indeed in all ntellectual pursuits A ripe scholar, excelling in lassical literature, proficient in several modern tongues including the peculiar dialects of the Mediterranean eoples of which he made an intimate first-hand study), n enthusiast for the fine arts of which he possessed more han a dilettante's knowledge, he preserved his mental lertness even in retirement through his wide circle of orrespondents in nearly every European country The nterruption brought about by the present war was a reat grief to him, as he had striven long and earnestly for better understanding of the British point of view in nany things But for the handicap of persistent ill ealth it is hard to put bounds to the height he might ave attained not only in his chosen profession but in ny walk of life Yet it is rather for his personal qualities hat he will dwell in the memories of his friends Com-assionate and forbearing, moved to rare anger only by a ale of wrong, ever ready not merely to respond to an ppeal for aid but to initiate the offer, and withal of esolute character, uncompromising in any matter where e deemed a principle to be involved, James Laing is assured a place on the roll of those men whose unobtrusive example has maintained the honourable standing of the liberal professions"

WILLIAM PARRY MORGAN

M D CAMB, B SC LOND, M R C S

Dr Parry Morgan, who died at Pontypridd on June 14 at the age of 66, was for more than twenty years in charge of the county public health laboratories at Cardiff The son of a well-known Cardiff solicitor, he received his early education in that town, going on to Cambridge where he was 16th wrangler in the mathematical tripos of 1898 He turned to medicine for a career and qualified from St Mary's Hospital in 1906, but mathematics remained one of his chief interests After qualifying he served on the staff of the Therapeutic Inoculation Department at St Mary's, where he acquired much of that deftness in technique and inventiveness in the matter of laboratory appliances that were the admiration of his friends He served on a mission investigating the incidence of epidemic pneumonia amongst the miners of the Rand In 1919, after retiring from the R A M C with the rank of captain, he returned to his native town as bacteriologist, and before his retirement in 1939 had become one of the best known and esteemed of Cardiff medical men Under his direction the county laboratory prospered, exercising a wide and beneficial influence in its district, not only as a centre for bacteriological diagnosis, but as a source of sympathetic help and advice to practitioners His early researches were mostly in the sphere of bacteriology and immunity, but the work in which he was most deeply interested was in the treatment of pulmonary tuberculosis by artificial pneumothorax Nearly thirty years ago he demonstrated the possibility of achieving by partial pneumothorax all that it was hoped to gain by complete collapse of the lung, and it gave him great satisfaction in his later years to see his doctrine, which had long been ignored, becoming accepted practice in many parts of the world

Parry Morgan was modest and retiring in character, but he was a man of strong principles, and his sincere pursuit of truth sometimes led him to take up an uncompromising attitude Nevertheless he was kindly and lovable, and he was held in high regard by his medical colleagues He leaves a widow and one daughter

WILLIAM WATSON PIKE

K C M G, D S O, F R C S I, MAJOR-GENERAL, LATE A M S

Major-General Sir William Pike, who died at Lincoln on June 29 at the age of 81, had a long and honourable record in the practice and administration of military medicine He had served in three continents In South Africa he took part in the relief of Kimberley, and in 1914 on the outbreak of war he sailed from India to act as D D M S of the Indian Cavalry Corps in France His work quickly won recognition and when he was promoted surgeon general in 1917 for distinguished service in the field he was already D M S of an army His earlier experience in Africa stood him in good stead when he was sent later in the same year on a special mission to East Africa to advise on the medical problems of that campaign, and the following year he was again chosen when a mission on medical administration was sent to India He retired from the Army in 1920 Pike was a genial, handsome Irishman Born in co Mayo he obtained the Irish conjoint qualification in 1880 and was given his commission two years later At this time he was playing rugby for Ireland, and was also a keen hockey player and a good shot In any capacity in life he was at the top of his form

ANDREW ST LAWRANCE BURKE

L R C P I

Dr Burke, who died at Kenilworth aged 74, was well known in Coventry where for thirty years he was a medical officer to the provident dispensary and became chairman of the board of guardians Son of a Galway lawyer he qualified from the Irish Royal Colleges in 1895 and filled varied surgical house-appointments ending with senior R S O at the City of Dublin hospital Before settling in Coventry he had some experience of general practice at Wolverhampton Early in the present for its birth-rate in the past five years has averaged about 14 and its death-rate 9 In 1939 infantile mortality was 33 9 and maternal mortality 1 75 The latter is a low record, attained by the reduction of fatal infection, in 2307 births there was only one death from puerperal fever Prevention of serious puerperal infections had got to a very satisfactory state by 1937 and then the introduction of the sulphonamides gave us a powerful remedy to combat failures of prevention Of the 1450 deaths which occurred in Ilford in 1939, more than half (763) were of people over sixty-five, 31 were aged 1–15, and 47 aged 15–25 The 78 deaths of these immature people were made up as follows 13 from violence and 2 from suicide, 13 from pulmonary tuberculosis (12 in people over fifteen), 5 from other tuberculosis, 7 from heart disease (all over fifteen), 3 from appendicitis, 4 from acute endemic infections, 7 from acute respiratory infections, and the remaining 24 from various causes

There are approximately 42,900 inhabited houses in Ilford of which 16,312 were inspected in 1939, bug-infestation was found in 49 There might be a few more infested houses which were not inspected, but the number would be small Other nuisances were detected in 1167, or roughly in 1 house of every 15 inspected The distribution of nuisances in houses not inspected naturally varies greatly with the energy of the sanitary inspector and his staff, but also with the nature of the property and the habits of the people To abate the nuisances detected 836 informal notices were served resulting in 707 abatements, and 312 statutory notices resulting in 253 abatements Of the statutory notices 258 were to provide dustbins

Infectious Disease in England and Wales

WEEK ENDED JUNE 28

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 840, whooping-cough, 5437, diphtheria, 909, paratyphoid, 74, typhoid, 37*, measles (excluding rubella), 8820, pneumonia (primary or influenzal), 666, puerperal pyrexia, 121, cerebrospinal fever, 192, poliomyelitis, 3, polio-encephalitis, 0, encephalitis lethargica, 5, dysentery, 78, ophthalmia neonatorum, 82 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on June 25 was 1526, including scarlet fever 168, diphtheria, 301, measles, 238, whooping cough, 469, enteritis, 18, chicken pox, 62, erysipelas, 30, mumps, 6, poliomyelitis, 1, dysentery, 5, cerebrospinal fever, 40, puerperal sepsis, 8, enteric fevers, 11 german measles, 8, encephalitis lethargica, 1, other diseases (non infectious) 67, not yet diagnosed, 93

Deaths —In 126 great towns there was 1 (0) death from scarlet fever, 4 (0) from enteric fever,* 22 (2) from whooping-cough, 9 (0) from measles, 18 (0) from diphtheria, 26 (2) from diarrhœa and enteritis under 2 years, and 5 (0) from influenza The figures in parentheses are those for London itself

Blackpool, Manchester, Birmingham and Newport (Mon) each reported a fatal case of enteric fever There were 4 deaths from whooping cough at Liverpool

The number of stillbirths notified during the week was 194 (corresponding to a rate of 41 per thousand total births), including 13 in London

---

* In Weekly Return No 26, for the first time ever paratyphoid and typhoid are listed separately in table 4 (Notification of Infectious Diseases) In table 2 however (Deaths) they are still pooled under a common heading which we have hitherto rendered as Enteric Fever

---

BEFORE the days of the sulphanilamide compounds quinine had a wide following in the treatment of respiratory infections, and in the minor ones it still has In the last few years it has been demonstrated that many infections are accompanied by an increased utilisation of vitamin C Messrs ORGANON LABORATORIES have now introduced a compound of quinine and ascorbic acid, Orgakinine, which they suggest should be tried in the pneumonias, influenza and colds when specific bactericidal therapy is withheld or has failed Orgakinine is made up in ampoules for intramuscular injection and in tablets for administration by mouth

Obituary

GEORGE FREDERIC STILL

K C V O, M D CAMB, LL D EDIN, F R C P

from a portrait by Mr Gerald Kelly R A

Sir Frederic Still, whose unexpected death was announced last week, was born in Holloway, in February 1868, the son of George Still, surveyor of customs He had his schooling at Merchant Taylors, thence to Caius College, Cambridge, where he took a first in the classical tripos and was Winchester prizeman In 1893 he qualified from Guy's Hospital, where as house-physician he came into the sphere of influence of James Goodhart, to whose teaching and example he owed his leaning to the study of disease in children From Guy's he went to the Hospital for Sick Children, to which institution he remained devotedly attached during all his active life There in various offices, beginning as house-physician, he worked happily for nearer forty than thirty years Other hospital appointments he held—when King's College Hospital opened a children's department Still was appointed physician in charge of it and of the academic chair created in 1906—and in time he had a great success as a consulting physician in the diseases of children, but no other work lay so near his heart as that at Great Ormond Street

His scientific reputation preceded his professional success, for quite early in his career at Ormond Street he did two pieces of work which made his name well known one established the entity of a chronic rheumatoid arthritis peculiar to childhood ("Still's disease"), the other identified the organism responsible for the affection described many years before by Gee and Barlow as posterior basic meningitis Gee had no great influence on Still—he had left Ormond Street before Still went there—but Barlow became the loved and admired inspiration of Still's career With Goodhart he collaborated in the later editions of that physician's successful textbook on children's diseases, and then he produced several further editions of the work unassisted He published articles, papers and lectures, nearly all on the more strictly clinical aspects of disease, many of these have permanent value, for he was an acute and accurate observer His industry was astonishing to his younger contemporaries, but he had little to distract him, for unlike most men he had no wish for the relaxation of social gatherings or sport, and the time which he might have spent on these he devoted solely to subjects connected with medicine Indeed it was with a somewhat amused surprise that in later life his friends learnt that he had become an ardent, though, as he often said, an extremely inefficient dry-fly fisherman, and later still enjoyed and added to the social amenities of the College Club

The passage of years gave him an almost unique position as a children's consulting physician, and at one period it was difficult to find a child of well-to-do and anxious parents who at some time had not been taken to see Still The International Pædiatric Congress which met in London in 1933, over which he presided, at once set the seal on his reputation and revealed even to his own profession the width of his learning, the geniality of his address and his fame among our foreign visitors For twenty years Still was the indefatigable chairman of the National Association for Prevention of Infant Mortality and when he retired in 1937 he received the K C V O It would be idle to enumerate the medical honours which fell to his lot, and all the varied responsibilities which he cheerfully assumed in public and private work He took his full share of both and relished both Suffice it that he had of later years ripened into a wider and mellower intellectual life than had in his earlier seemed probable At Cambridge he had been a notable classical scholar and the love of the classics returned to him with

Notes, Comments and Abstracts

PREMARITAL AND PRENATAL TESTS FOR SYPHILIS *

By J. V. DePorte, Ph.D.
DIRECTOR OF THE DIVISION OF VITAL STATISTICS, NEW YORK STATE DEPARTMENT OF HEALTH

On Jan. 1, 1941, premarital tests (for syphilis only, or for syphilis and other specified conditions) were required by 20 states in the U.S.A., prenatal tests for syphilis by 19 states, and both tests by 12 states.

Premarital and prenatal tests		Premarital test only	Prenatal test only
California	New Jersey	Connecticut	Delaware
Colorado	New York	New Hampshire	Iowa
Illinois	North Carolina	North Dakota	Louisiana
Indiana	Pennsylvania	Oregon	Maine
Kentucky	Rhode Island	Tennessee	Massachusetts
Michigan	South Dakota	Virginia	Oklahoma
		West Virginia	Washington
		Wisconsin	

PREMARITAL EXAMINATION

In all of the 20 states both partners must have a premarital examination for syphilis and in 8 states the examination covers all venereal diseases. In addition, North Carolina requires an examination for epilepsy, insanity and tuberculosis, and Oregon requires one for chronic alcoholism, drug addiction and feeblemindedness. The examination must be made within a period which varies from 10 to 40 days before the issue of the marriage licence. The blood-test must be standard and recognised, and must be made in an approved laboratory. All applicants for a marriage licence must submit a doctor's certificate. The state of Virginia is unique in that *it allows people with syphilis in the communicable* stage to marry without a court waiver, because it is considered "that by allowing infected individuals to marry more cases will be brought to light and treatment, and fewer persons will leave the state to marry or resort to illicit relationships because of fear of being prohibited from marrying." The Virginia law also provides that if the report is positive the doctor must take a thorough medical history, make a physical examination, and have another blood-test made. If there is no doubt that the applicant has syphilis he must be informed and if he still wishes to marry the doctor must inform both parties of the fact and of the possibility of the transmission of the disease. If both still wish to marry, they must sign a statement to that effect and agree to take treatment so long as such treatment is deemed necessary by the state health department. Virginia already had on its statutes a law penalising people who knowingly transmit venereal diseases. In 16 states people with infectious syphilis or with syphilis which is likely to become communicable, may in an emergency or extraordinary circumstances marry with the permission of a court. The issue of a marriage licence is governed in 17 states by the doctor's opinion as to whether the disease is or is not likely to become communicable. In Illinois, Michigan, Oregon, South Dakota, and Wisconsin the law specifically requires that the doctor's opinion with regard to freedom from syphilis shall be accepted only if the blood-test is negative, and the issue of a marriage licence in these states (except South Dakota) depends on the approval of the state department of health. Only 3 states provide for an appeal in cases where a marriage licence is refused. The fees for laboratory tests and physical examinations vary greatly. In 8 states tests may be obtained free and in 4 others no charge is made for those who are unable to pay. In North Dakota the fee must not exceed 50 cents, in Oregon $5, and in Wisconsin $2. In 6 states positive reports must be filed with the department of health or health office. In all but one state (Colorado) penalties for the violation of the law are provided. These consist of fines ranging up to $1000, sometimes with prison sentences as well.

PRENATAL EXAMINATION

In all of the 19 states which provide for prenatal examination it is confined to blood-tests for syphilis. In North Carolina the responsibility for having such a test made is placed not only on the professional attendant but also on the pregnant woman, while in the other states it is the professional attendant who is legally responsible. In 10 states the blood of every pregnant woman must be tested for syphilis; in 7 others a test must be made only at the request or with the consent of the pregnant woman; in Massachusetts the attending doctor need not make a blood-test if one has already been made during the pregnancy by another doctor; in Indiana the test is waived if the pregnant woman is opposed to medical examination for disease. The laws of 9 states require that a blood-test shall be made at the first professional visit or within 10 or 15 days afterward; Indiana specifies "at time of diagnosis"; Iowa within 14 days; Maine "during gestation"; North Carolina "upon request of woman"; Rhode Island within 30 days after the first professional visit. Provision for tests without charge is made in 11 states, in 2 others the tests may be made free if the patient is unable to pay. California is the one state in which the law provides that if the accuracy of the test is questioned the state department of health must accept a specimen for checking. The laws of California, Iowa, Kentucky and Maine provide that the results of tests must be filed with the state department of health. The Michigan law lays down that the results are not public records but are available to local health officers and to doctors treating the patient. As a rule birth certificates must show whether or not a blood-test for syphilis was made, and if so its date, but in 11 states the law specifically provides that the birth certificate shall *not* show the result of the test. None of the 19 states provide penalties if the pregnant woman refuses to have a test made.

---

[*] Based on a summary of recent state legislation prepared by Anita E. Bowden, Ph.D., of the U.S. Public Health Service.

STATE CONTROL OF HOSPITALS AND MEDICAL SERVICES

A SAMPLE OF PUBLIC OPINION

Public attention is today turning to the possibility of extending the scope of central government activity to embrace the medical services. This results perhaps from two main war-time developments:—

(i) The incursion of central government into realms hitherto thought private matters.

(ii) Realisation of the importance of matters affecting personal health and medical treatment, made acute by air-raid casualties, food rationing, disturbed sleep, evacuation of children, and the like.

Public sentiment is of obvious importance for planning post-war reconstruction or adapting our social organism to war-time needs.

The British Institute of Public Opinion, an independent organisation engaged in sounding this opinion on matters of social and political interest, has recently surveyed public sentiment on the question. A balanced sample of the population was asked by the institute's investigators to state its preference for one of the following three proposals:—

(*a*) All doctors and hospitals under State control with their services free as education now is.—*Yes*, 55%

(*b*) An extension of the panel system to include everybody.—*Yes*, 30%

(*c*) *Having a private doctor whom you pay for his* visits and medicine.—*Yes*, 15%

It will be noted that the three proposals are graded so that the second (*b*), though not excluding the possibility of private voluntary hospitals, yet expressed a desire for an extension of State organisation to pre-hospital treatment.

THE METHOD

The method of investigaton is well known and regularly used by scientists. It consists in recording the reactions, in the matters under inquiry, of a balanced sample of the population. The sample used is based on careful statistical and social analyses of the population, and due weight is given to the principal groupings into which all century the Coventry dispensary which had become very popular was criticised for its canvassing of the public and Dr Burke with two of his colleagues brought a successful action in the High Court against the British Medical Association for professional boycott Dr Burke who was proud of being able to trace a family tree to Norman times had a pretty taste in equipage, and later developed a conservative attachment to cars which had served him well He was a good judge of old prints He leaves a widow and a daughter

Acting Squadron-Leader **David Alan Hope Robson**, who lost his life in an air crash on June 26, was born in 1908 and graduated M B from the University of Edinburgh in 1933 After holding house-appointments at the Children's Hospital and City General Hospital, Sheffield, he spent four years in general practice at Wallington, Surrey, where he was also hon medical officer to the Carshalton and Beddington War Memorial Hospital He entered the medical branch of the Royal Air Force on a short-service commission in 1939, and from the outbreak of war until April, 1940 he served in France On his return he was posted to an operational unit Robson qualified as a pilot this year, he was particularly interested in research problems in connexion with flying at high altitudes He lost his life when a new type of aircraft crashed

Flight-Lieutenant **Denis William Mahon** was seriously injured in a flying accident on June 9, and died shortly afterwards at the age of 26 He qualified M R C S in 1938 from the London Hospital where he was a member of the O T C He demonstrated at the medical college in applied physiology, histology and applied pharmacology, and after holding house-appointments at Poplar Hospital, and the Royal Berks Hospital, Reading, he was commissioned in the R A F Volunteer Reserve in November, 1939 From February till June last year he served in France, when he was appointed medical officer to a bomber squadron

Dr **A Lasnet**, news of whose death on Dec 14, 1940, has been received from the International Office of Public Health, was delegate for Indo-China and later for Algeria on the permanent committee of the office Lasnet had had wide experience in every French African colony and in Indo-China and was in charge of the health services of the French Army of Occupation on the Rhine until 1924, when he became inspector-general of the French colonial medical services In 1924 he joined the committee of the office and in 1936 he undertook a mission to Spain to investigate the epidemic and sanitary situation on behalf of the health committee of the League of Nations In 1937 and 1938 he was in charge of one of the three health units sent out to China by the League His works include many studies on epidemiology, hygiene and social medicine and he took especial interest in yellow fever and in the Mecca pilgrimage

Medical News

Royal College of Surgeons of England

Election to the Council —On July 3 four fellows were elected to fill the vacancies caused by the retirement in rotation of Mr Burgess, Mr Souttar and Mr Cope, and by the death of Mr R C Elmslie The result of the poll was as follows —

	Votes
Arthur Henry Burgess (Manchester)	608
Henry Sessions Souttar (London)	604
Vincent Zachary Cope (St Mary's)	528
Ernest Frederick Finch (Sheffield)	492
Philip Henry Mitchiner (St Thomas's)	480
Sir Harold Gillies (St Bart s)	467
Reginald Martin Vick (St Bart's)	429

In all 1097 fellows voted , in addition 7 votes were found to be invalid Mr Burgess, Mr Souttar and Mr Cope are all elected for the full period of eight years, and Mr Finch acts as substitute member for the late Mr Elmslie until July, 1946

Society of Apothecaries of London

D A Ogden, St Mary's, having completed the final examination, has been granted the diploma of the society, entitling him to practise medicine, surgery and midwifery

University of St Andrews

On June 27 the following degrees were conferred —

M D —R Y Dunlop and Jean L Hallum

M B , Ch B —Nancy Young K G Lowe, A W K Main E L McQuitty, Laeticia J W Douglas Anne M Wood, an Gwendoline M Sturrock (with commendation) , Mary O Adams Margaret C Barnet, Elizabeth S Bayne Samarendra C Chatterj Francis E Clynick, Angus Everard, Joyce M Fleming, R Flynn, J O Forfar, Philippa E Gaffikin, Sheila Graham, J Law, Alexander MacKenzie, R S MacKenzie, Alexander MacLear F A Macrae, J M S Manson, N D Paton, J M Robertson Kathleen Robertson, Constance F Ross, A E D Sanjana, Agnes C Swales, K A Swales, and A K Tulloch

University of Manchester

At recent examinations the following were successful —

M D

P R Evans, and J A Hobson

FINAL EXAMINATION FOR M B , CH B

S S Rose (with second class honours) , E P Abson R G Bal John Ball, E A Cachia, D M Coates, B O Dowdell, B I Eame Jeanne M Edwards Elozor Feinmann, Alan Glass J C Greenwoo P G Griffiths, E G Hall, Frances A Hepburn, Margaret Jacque R P Jepson, Susanne M Lempert, D C Little, F S Moone T E Parry, John Thompson, Vera Waine, F R Wilde, Lion Wise, Basil Wolman, and P B Woolley

University of Liverpool

At recent examinations the following candidates we successful —

M D

F C Deller

FINAL EXAMINATION FOR M B , CH B

N B Jones (first class honours) , B B Evans, and N O I Gibbon (second class honours)

Part III —Katharine E Ainsworth, G M Ardran, W W Aslett, Aileen M Barry, W H Berry R S Cook, R T Davie J A Donnellan, C V Donnelly, B K Ellenbogen, J J Ennit H E D Flack, H W Forshaw, G L Gamble, A J Goldma H R Gray, J J Hargadon, I J Harris, J H Hughes, Lillie Jackson Katie H Jones, Mair E Jones, W J Jones, Mary Jorda A C Kirby, C A Kovachich, C C Laird, T E Lamb, D Lesli T B McMurray, M Makin, Lucy D Meyrick, E L Moore, Moorhouse, P P Newman, J A B Nicholson, J D F Norma C N Partington, D E Paterson, H C Percy Hughes, G Pimblett, Joan E M Potts, A G Rickards, F S Rickards Rosenthal, C N Samuell, G D Scarrow, G L Shatwell J Swithinbank, W G Taaffe E Walker C W Walton, A S White head, J K Wilson, J Winter, and F J Zacharias

THE QUANTITATIVE ADMINISTRATION OF ETHER VAPOUR

R R MACINTOSH,
D M OXFD, D A

K MENDELSSOHN,
PH D BERLIN

Nuffield Department of Anæsthetics, University of Oxford

AN anæsthetic which is in the gaseous state at N T P can be administered in any desired quantity or concentration by regulating the measured rate of its flow The object of the work to be described in this and the following papers was to devise means by which the anæsthetist shall be able to control in a similarly simple and accurate manner, the composition of a mixture containing the vapour of a liquid anæsthetic The fact that a liquid anæsthetic is stored in the liquid state and administered in the gaseous state confers great advantages of portability and compactness At the same time this fact makes the problem of its quantitative administration more difficult because an intermediate process of vaporisation is necessary

A method of historic interest of administering the vapour of a liquid anæsthetic quantitatively is that of Snow, who in 1849 introduced a measured quantity of liquid chloroform into a large bag, sufficient when the bag was filled with air to form a mixture containing 4% of chloroform vapour The method proved cumbersome and was abandoned, because, said Snow (1858), " it seemed necessary to sacrifice a little of absolute perfection to convenience " The method was revived for a short time by Clover (1862) More practical methods of administering chloroform dosimetrically were introduced by Vernon Harcourt (1903), Levy (1905), and more recently by Rowling (1932), but for reasons which will be apparent later none of these methods is suitable for ether, of which a much larger volume must be evaporated in order to obtain a corresponding degree of anæsthesia

In order to explain the present method by which this problem has been dealt with, it is necessary to refer briefly to the physical laws governing the vaporisation of liquids The concentration of vapour in the atmosphere above the surface of a liquid depends solely on the temperature of the liquid If the temperature changes the concentration of vapour in the air above the liquid changes accordingly The vapour-pressure curve for ether (fig 1) shows the strength of the saturated ether-air mixture corresponding to temperatures ranging between −20° C and 40° C , expressed both as partial pressure in mm Hg and in volume per cent of ether vapour in the mixture This strength is about 10% at −17° C , 25% at 0° C , 50% at 17° C (room temperature) and 100% at 34° C , the boiling-point of ether This gradual variation of the vapour concentration with temperature might seem to offer a means of administering a mixture containing any desired strength of ether vapour simply by changing the temperature of a vessel containing liquid ether, but unfortunately, for practical reasons, the construction of a device which allows such rapid well-controlled changes of temperature is not feasible We have therefore directed our attention to maintaining in an ether container a constant high concentration of ether vapour, diluting this with air or other gases in such a way that the percentage of ether vapour in the mixture delivered to the patient is known and can be altered at will

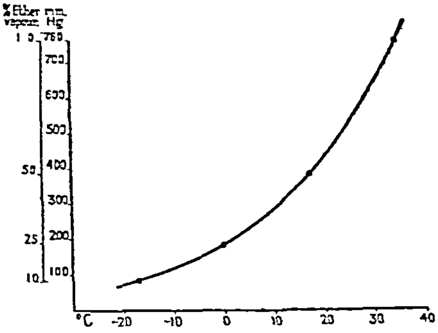

FIG 1—Vapour pressure curve for ether

In order to ensure this constant and high concentration of ether vapour it is necessary to keep constant the temperature of the liquid ether within the container It is here that we meet with our first difficulty The vaporisation of a liquid is a process which involves consumption of heat—for example, the transformation of 1 gramme of liquid ether into ether vapour of the same temperature requires 90 calories Unless this " heat of vaporisation " is furnished from outside the liquid will cool, and there will be a continual decrease in the strength of the vapour above the liquid

The jacket of warm water commonly used round the familiar Boyle's bottle does not provide this heat in a satisfactory manner If the heat content of such a jacket is to be adequate the size of the jacket will be unwieldy, since the initial temperature of the water must not exceed the boiling-point of ether, 34° C Further, the temperature of such an assembly will not remain constant, because the temperature of the water will fall as heat is taken from the system

CRYSTALS AS A HEAT RESERVOIR

The use of an electrical thermostat while theoretically satisfactory is not so in practice, because electricity is not always available, and because of risks of ignition Instead we have made use of the latent heat of a subsidiary substance to act as a *heat reservoir* at constant temperature It is well known that if heat is added to or lost from a vessel containing melting ice the temperature of the ice-water mixture does not change There is an increase in the amount of water present when heat is added, or in the amount of ice when heat is taken away, in each case at the expense of the other phase Thus any changes in heat content of the system either melt ice or crystallise water, but do not result in changes of temperature Such a thermostat is well suited to our purpose, but instead of ice we must choose another crystalline substance with a melting-point lying at a more convenient temperature The maximal concentration of the vapour desired determines the temperature to be maintained within the ether container, and the melting-point of the heat-reservoir substance must correspond with this temperature

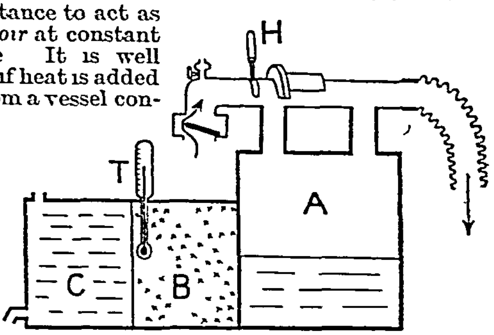

FIG 2—Scheme of ether vaporiser A ether container, B heat reservoir containing crystals, C hot-water chamber, H tap for controlling ether concentration, T thermometer

The general scheme of the new type of ether vaporiser is shown in fig 2 A is the container in which ether is evaporated, B the heat reservoir containing the crystals, and C is a chamber into which hot water is poured to provide heat to melt the crystals Let it be assumed that just sufficient hot water has been put into the chamber C to melt all the crystals in the reservoir B When ether vapour is taken out of the container A, more ether will evaporate in order to restore the original concentration of vapour above the surface of the fluid ether The temperature of the fluid ether does not fall, because the heat used for the evaporation is furnished from the reservoir B, in which an equivalent amount of molten " reservoir " substance crystallises This process goes on at constant temperature until all of the liquid in the reservoir B is solidified, which will be shown by a sudden fall in the reading of the thermometer registering the temperature of B In order to re-melt the crystals hot water is again poured into C There is no need for the temperature of the water to be below the boiling-point of ether, for the crystals in B will act as a thermal buffer, taking up heat at any higher temperature but releasing it only at the temperature of their melting-point members of the population fall, in one capacity or another These groups, known as "controls," include geographical dispersion, age and sex distribution, economic or income categories and the main occupational groupings Recent changes resulting from evacuation, mobilisation and the bombing of certain areas are of course incorporated in so far as their effects can be estimated

The degree of probable accuracy to be expected by interviewing different numbers of people may be accurately defined statistically If (say) 900 people are questioned and their opinions divide evenly on a given subject, the mathematical chances are 997 in 1000 that the margin of error will not be greater than 5% Should opinion divide unevenly then the margin of error will be even smaller The sample used is such that the greatest margin of error expected is between 3% and 4% with the least favourable division of opinion

ITS APPLICATION

In the light of this a total of 85% for some kind of State organisation of pre-hospital treatment is specially significant, and contrasts with 15% expressing preference for private doctors This was so in spite of frequent criticism of certain aspects of the panel system as now operating, expressed in such comments as —

> "Most men feel the panel system does not work too well—there is too great a dividing line between the doctors' treatment of the panel patient and the paying patient"

There were, too, certain reservations in the public mind on State control which were summed up in the comment —

> "Afraid State doctors would be like going to a Relief doctor—maybe they would treat us like dirt"

As opposed to these fears was the opinion of those favouring State control expressed in the typical comment —

> "The voluntary system means hospitals burdened perpetually with debt which must hamper efficiency"

Interesting divisions of opinion are revealed by a closer examination of the groups questioned Figures for the various groups were

INCOME GROUPS	*State control*	*Extension of panel*	*Private doctor*
Higher	37	23	40
Middle	56	23	21
Lower	55	32	13

Middle and lower income groups (£10 a week and under) approve, to the same extent, of State control 56% and 55% respectively as opposed to 37% approval amongst the upper income groups (over £10 a week) The latter group voted 40% for private doctors as against 21% in the middle income group and 13% in the lower income group On the other hand opinion in the upper and middle income groups with 23% approval for an extension of the panel system contrasted with 32% amongst the lower income group

AGE GROUPS	*State control*	*Extension of panel*	*Private doctor*
21–29	58	29	13
30–49	58	23	14
50 and over	45	33	22

Clear differences in attitude were noticeable in the age groupings questioned Of those under 50 years of age 58% were in favour of State control as opposed to 45% approving in the over 50 years age group The over 50's were on the other hand more inclined to favour an extension of the panel system or having a private doctor This probably reflects the fear in old people (expressed in a reported comment noted above) of harsh treatment by dis-interested doctors

SEX GROUPS	*State control*	*Extension of panel*	*Private doctor*
Men	58	29	13
Women	52	30	18

Men are slightly more in favour of State control than women, who in the same small degree incline towards private doctors The difference between the opinions of the sexes is by no means as large as the differences noted amongst other groups

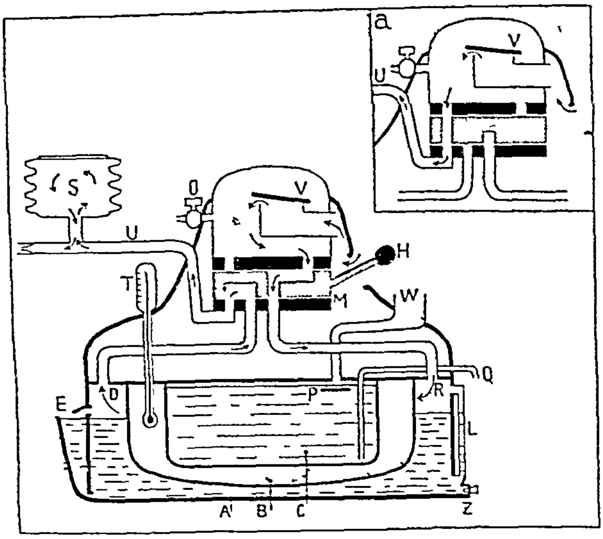

FIG 2—Modified vertical section through Oxford Vaporiser No 1 A ether chamber, B heat reservoir containing calcium-chloride crystals, C hot water chamber D exit for air plus ether vapour E ether filler H lever for controlling ether concentration, L ether level indicator M mixing tap assembly, O tap for oxygen, P baffle plate, Q water outlet R inlet for air S bag, T thermometer U tube to mask, V inlet valve, W filler for hot water, Z plug for draining ether In inset (a) the mixing tap is turned so that air passes direct to the patient

by the omission of fins from the walls of the containers Fig 3 is a sketch of the apparatus

The hot water chamber (*C*) —Hot water is poured in through the filler W and impinges on the baffle plate P In this way the freshly added hot water occupies the upper part of the chamber and displaces the cooled water through the outlet tube Q When the chamber has been completely filled with hot water, the stream flowing from the outlet changes quite suddenly from cold to hot

The calcium chloride chamber (*B*) is a cylindrical chamber the bottom of which is rounded so that bubbles cannot be trapped underneath it It contains the bulb of the thermometer T which registers the temperature of the calcium chloride After it has been filled this chamber is sealed off by the manufacturers and it should not be opened The hydrated calcium chloride does not deteriorate with time, but if exposed to air the crystals lose water and become inefficient for our purpose

The ether container (*A*) is filled through the funnel E, whose upper rim is so arranged that the chamber cannot be overfilled If by mischance hot water is poured into this filler it would not enter the chamber because of the constriction at the apex of the funnel The hot ether-water mixture would instead be blown back from the filler with considerable violence The ether level in A is shown by the level indicator L, and Z is a drain plug through which ether may be drained away

The inspiratory valve (*V*) *and mixing tap assembly* (*M*) — When the patient breathes, air is drawn into the vaporiser through the slot in the outer container from which the ether concentration control lever H projects The air then passes through the inspiratory valve V, whose action can be observed through the transparent dome (D in fig 3) If required oxygen may be added through the tap O

The mixing tap consists of three discs in which ports are cut The upper and lower discs are fixed and the intermediate one can be rotated about a central axis by moving the lever H By means of the mixing tap the air can now be (1) diverted wholly or in part over the surface of the ether, or (2) by-passed directly to the patient, who thus receives air only In fig 2 the tap is shown in the position in which all of the air reaching the patient passes through the ether chamber, the pathway being marked by small arrows Inset (a) shows the course taken by the air when it is passed direct to the patient without any part of it passing through the ether chamber The control handle H can be adjusted to any intermediate position , the figures above it (see fig 3) indicate the percentage of ether vapour (v/v) reaching the patient

The spirometer type bag (*S*) is lightly spring-loaded so that it tends always to remain expanded In normal use its action is to draw air gently through the vaporiser during the intervals between the patient's inspirations When the patient inspires, part of the contents is drawn from the bag, but the spring loading cannot produce any resistance to inspiration since air can at all times be drawn freely through the inspiratory valve V Rebreathing into the bag does not occur because of a one way valve placed between the mask and the bag When required the bag can be used as a pump to draw air over the surface of the ether and to deliver the resultant mixture to the patient This will be found of value during induction, and when an air-tight junction cannot be made between the face and mask, as for example during tonsillectomy The bag can be used too for artificial respiration , the ether indicator is set at zero, the mask held firmly to the face, and the lungs inflated with air by pressure of the anæsthetist's hand on the bag

In fig 3 a portion of the outer wall of the apparatus has been cut away, so that the outer wall of the calcium-chloride container and the radial fins come into view These fins project almost to the outer wall of the ether chamber, dividing it into twelve separate compartments Wicks are placed in each compartment These considerably increase the effective ether surface and since they are applied closely to the wall of the calcium-chloride chamber their temperature does not fall appreciably as evaporation takes place Slots are cut in the fins to allow the air to pass from the inlet tube (R, fig 2) to the exit tube (D fig 2) The arrangement of the slots is such that the current of air is made turbulent and passes close to the surface of the ether no matter what the ether level may be In this way, provided the position of the control tap remains unaltered, a constant concentration of ether vapour is delivered to the patient irrespective of the amount of ether in the apparatus

OPERATION OF THE VAPORISER

The ether chamber is filled Water, as hot as available, is poured into the water filler W to displace the cold water which escapes from the outlet tube Q The stream of water emerging from Q is cool at first, but quite suddenly changes to hot When this occurs no more hot water should be poured in After a few minutes it will be seen that the mercury in the thermometer T, which for convenience has a horizontal stem (fig 3), stands above the mark t_1 The apparatus is now ready for use the concentration of ether vapour delivered from it being determined by the position of the control handle H

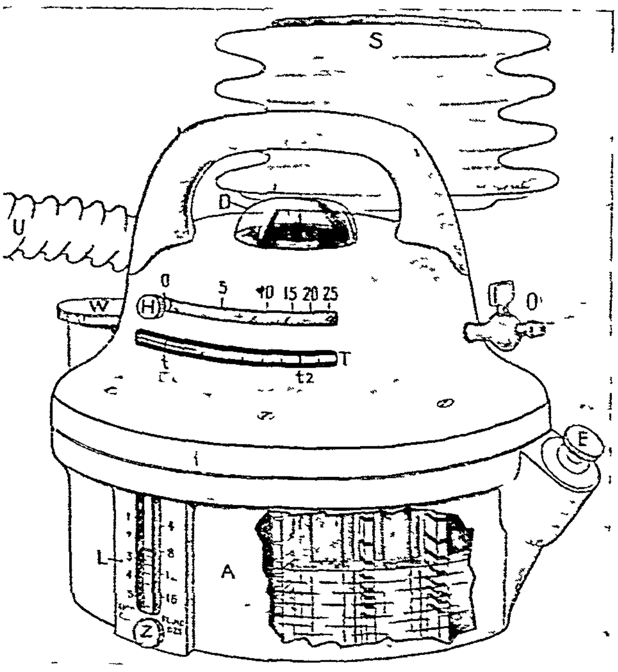

FIG. 3—Sketch of Oxford Vaporiser No 1 with part of outer wall cut away For normal working the thermometer reading should be between the marks t_1 and t_2 D glass dome for observing inspiratory valve , other key letters as in fig 2

Both the vaporisers to be described in the following papers work according to the principle outlined In the Oxford Vaporiser No 1 the temperature of the ether is kept *below* its boiling-point by choice of a suitable reservoir substance, and the machine is in fact an ether-vapour inhaler from which a constant supply of highly concentrated ether vapour is available and may be diluted with air to any desired strength by means of a calibrated mixing tap In the Oxford Vaporiser No 2, by the use of a reservoir substance whose melting-point is *above* the boiling-point of ether the concentration of ether vapour in the container is maintained at 100%, pure ether vapour is thus available and can be measured and then administered by methods similar to those used with other anæsthetic gases

The questions with which we have dealt so far are all related to the heat balance which must obtain within the system, and we have so far made the assumption that equilibrium is reached instantaneously Unfortunately this is not the case in practice It is well known that it is very difficult to saturate with ether vapour a stream of air passing over an ether surface, and also that it may take a long time before thermal equilibrium is reached between adjacent containers the contents of which are initially at different temperatures In the construction of vaporisers, therefore, we have not only to ensure that sufficient energy is furnished for the evaporation and that this evaporation takes place at a constant temperature but we must also see that attention is given to the problems of heat transfer, heat insulation, and the mixing of the anæsthetic vapour with air or other gases It is not possible to give a simple general solution of these problems, so that the way in which they have been dealt with is outlined in the descriptions of the two vaporisers

SUMMARY

The physical principles involved in the vaporisation of any liquid anæsthetic are discussed In order to maintain a constant supply of vapour it is necessary to keep constant the temperature of the liquid Two requirements must be satisfied First, an amount of heat equal to the latent heat of evaporation of the liquid must be supplied, this is done conveniently by utilising the latent heat of crystallisation of a “ reservoir ” substance which has previously been melted Secondly, the heat transfer from the molten reservoir substance to the liquid anæsthetic must be sufficiently rapid If these are satisfied, a measured amount of the vapour of a liquid anæsthetic can be delivered to a patient just as easily as a measured amount of any anæsthetic which is a gas at room temperature

The principle of utilising the latent heat of crystallisation has been used for the purpose of maintaining bacteriological specimens at constant temperature by Mislowitzer (1937) and Harrison (1937) We have to thank Colonel L W Harrison for his helpful interest in the initial stage of this work

THE OXFORD VAPORISER NO 1

H G Epstein, PH D BERLIN

R R Macintosh, D M OXFD, D A
K Mendelssohn, PH D BERLIN

Nuffield Department of Anæsthetics, University of Oxford

The operation of this ether inhaler depends on the principles outlined in the previous paper A diagrammatical sketch of the apparatus is given in fig 1 A, B and C contain ether, the reservoir substance and hot water respectively (cf fig 2 of the preceding paper) The mask G is placed on the patient's face so that on inspiration air is drawn through the valve V The air goes straight to the patient (full arrows), or by means of the mixing tap H it can be directed over the surface of the ether (broken arrows) Any concentration of ether-air required for anæsthesia can be attained by setting the tap suitably

The dimensions of the various chambers are determined by (1) the amount of ether vapour which is to be furnished in a given time, and (2) the frequency with which it is convenient to supply heat by refilling the apparatus with hot water In order to fulfil comfortably the maximum demands which may be made upon the machine during induction and maintenance, the vaporisation of 15 fl oz of ether per hour has been provided for The vaporisation of this amount of ether requires 28,000 calories If we decide that the hot-water chamber is to be refilled once every 60 minutes, then we must be able to add 28,000 calories each time we refill, and this amount of heat will be furnished by 400 c cm of boiling water as it cools from 100° C to 30° C, the melting point of the reservoir substance The capacity of the hot-water container is thus determined at 400 c cm

Hydrated calcium chloride ($CaCl_2$ 6 H_2O) was chosen as a suitable reservoir substance Various other inorganic and organic compounds with melting-points in the neighbourhood of 30° C were tried but rejected because they were too active chemically or were subject to considerable supercooling The minimum amount of calcium chloride which can be used is that amount which will just be melted completely by the addition of 28,000 calories, since, if less calcium chloride is used, the heat added in filling the hot water chamber might completely melt the substance and then raise its temperature above the boiling point of ether By calculation, this minimum amount of calcium chloride is 700 grammes In practice, however, it is desirable to use considerably more than this minimum amount This is a safeguard in case the water container is inadvertently refilled with boiling water twice in rapid succession—although such a mistake can occur only if the reading of the thermometer is ignored In order to provide a considerable margin of safety we have therefore incorporated a calcium-chloride container with a capacity of 1300 g

Good heat transfer must be provided between the hot water and the calcium chloride, and between the calcium chloride and the ether, on the other hand, direct transfer of heat between the hot water and the ether must be prevented These conditions are achieved by arranging the containers concentrically The hot-water container C is cylindrical and placed centrally, surrounding this is the calcium-chloride container B, and outside this again the ether container A Since the ether container is maintained at about 30° C, heat loss from the apparatus is small because the temperature difference between its outside wall and the surrounding air is slight Heat exchange between the containers is increased by making them of an alloy of good heat conductivity, and by equipping the walls with radial fins

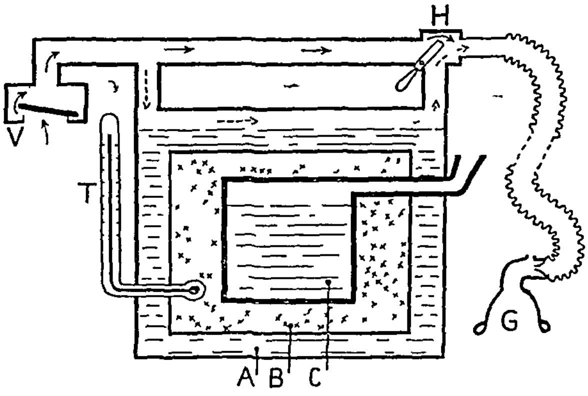

FIG 1—Diagram of Oxford Vaporiser No 1 to show general principles A contains ether, B crystals and C hot water G mask, H mixing tap, V inlet valve, T thermometer

DETAILS OF CONSTRUCTION

A modified cross-section through the actual model is given in fig 2 In order to represent as much as possible in one plane, the layout has been somewhat distorted, and various parts have been simplified—for example, The vessel for the reservoir substance, like the inner vessel, is made of metal of high thermal conductivity and fins are inserted radially These pass into the reservoir substance and through into the water contained in the outer vessel (fig 2) This construction ensures that heat from hot water poured into the outer compartment reaches the reservoir substance as rapidly as possible A funnel (W in fig 3) is provided above the water compartment whereby the water is poured in By an arrangement of tubes this hot water is directed first to the region of the flowmeter, which is thus warmed prior to the remainder of the apparatus, so that risk of condensation of the anæsthetic vapour in the flowmeter is obviated An outflow for displaced cool water is provided, Q

At the bottom of the vessel containing the reservoir substance there is a safety device in the form of a fusible metal plug The metal is chosen to melt at about 10° C above the melting-point of the reservoir substance If by accident the water container is refilled too many times so that all the reservoir substance is melted, before the temperature, and therefore the pressure, in the inner vessel can rise appreciably, the metal plug will melt and allow the molten substance to run out

When the reservoir substance is heated to its melting-point the pressure in the inner vessel rises above atmospheric, and therefore it would be impossible to fill this vessel with anæsthetic liquid without the aid of a pump A pump P and safety device have been constructed which will deliver anæsthetic liquid to the inner vessel, but no air This obviates the danger that the pressure in this vessel might be increased unduly by pumping in air , also, it prevents the production, under pressure, of a possibly explosive mixture of anæsthetic vapour and air The pump is of the hand-operated piston type, the piston being fitted with rings to minimise leakage It is contained in a small tank filled with the anæsthetic liquid so that any leakage which may occur merely results in the liquid returning to the main bulk Suitably arranged non-return valves allow the passage of liquid to the inner vessel In the small tank there is a float which closes the orifice leading to the pump when the level of liquid in the tank falls to within a short distance of this orifice, thus preventing entry of air into the pump Loss of heat from the warmed part of the apparatus to the pump via the connecting pipe is minimised by interposing a short length of bakelite tubing

In order that the amount of anæsthetic liquid present in the inner vessel may be ascertained, a liquid-level gauge L is provided This is recessed into a bakelite block which is mounted in the wall of the middle vessel alongside the metal sheath of the flowmeter

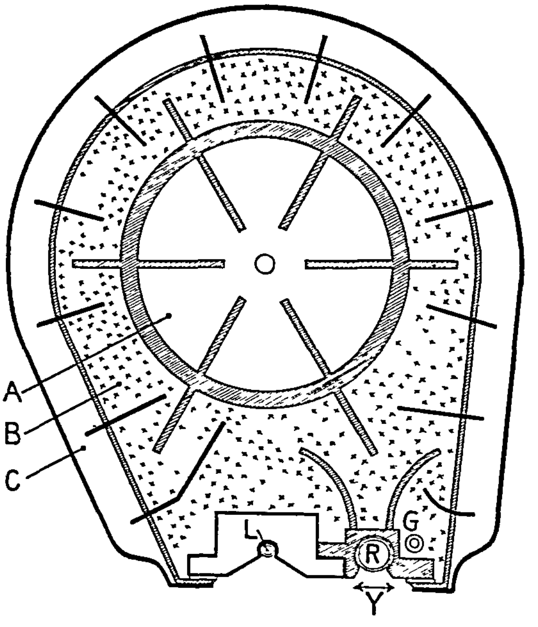

FIG 2—Horizontal section through Oxford Vaporiser No 2 A, B C G and R as in fig 1 L gauge showing level of liquid anæsthetic, Y window in metal sleeve

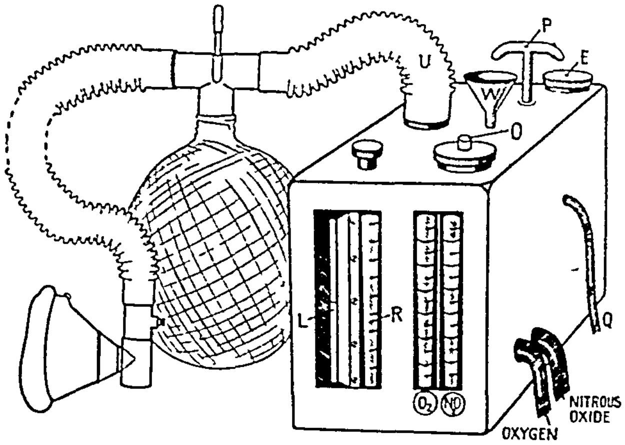

FIG 3—Sketch of Oxford Vaporiser No 2 E filler for ether, L fluid anæsthetic gauge, O press button actuated emergency oxygen supply, P pump for use when refilling ether chamber, Q outflow for cool water, R flowmeter for anæsthetic vapour, U connecting tube, W funnel for hot water, O_2 and N_2O flowmeters for oxygen and nitrous oxide

OPERATION OF THE VAPORISER

The method of putting the apparatus into operation can be described conveniently with special reference to ether When this liquid is used, para-dichlorobenzene has been found a suitable reservoir substance The melting-point of a moderately pure sample is usually about 52° C From the data given in International Critical Tables (vol i, p 196, 1926 , vol v p 130, 1929) it can be calculated that the latent heat of fusion is approximately 43 calories per c cm A rotameter graduated in c cm of ether vapour per minute, at room temperature, should be fitted into the sheath , also, a fusible metal plug melting at about 62° C should have been fitted before putting in the reservoir substance Ether is poured into the tank through aperture E and pumped into the inner vessel until this is full Three lots of two pints each of hot water (approx 85° C) are poured into the water compartment at five-minute intervals The amounts of reservoir substance and of hot water are chosen so that when enough heat has been stored to vaporise all the ether in the inner vessel there remains enough unmelted reservoir substance to absorb the heat from a further filling with hot water This provides a reasonable safety margin against filling too frequently with hot water If, however, this safety margin is exceeded the temperature of the reservoir substance will rise and the fusible plug previously described will operate While the three amounts of hot water will provide sufficient heat to vaporise all the ether contained in the inner vessel, it is preferable, if more ether is likely to be required, to refill before the supply has become exhausted To do this the inner vessel is refilled from the tank by operating the pump, and two more fillings of hot water are poured in allowing a five-minute interval

Provided that the flow of gases (essentially the flow of oxygen) is maintained, mixtures of any desired concentration can be produced by adjusting the control valves to give suitable rates of flow as measured by the respective flowmeters

To prevent total failure of the supply of any gas the usual precaution in anæsthetic practice of using a pair of cylinders, one always full, is observed A lightly loaded inspiratory valve V opening to the air is also provided and comes into play only if an insufficient total volume of gas mixture is available to the patient Should it be desirable at any time to inflate the patient's lungs with oxygen this can be done readily by means of a valve O actuated by a press-button which permits oxygen to pass under pressure to the patient, without passing through the flowmeter

As the work of Epstein * shows, the temperature of the inspired mixture during its passage from the apparatus to the patient falls to slightly above room temperature Condensation of ether will not occur in the tube leading to the patient provided that the partial pressure of ether in the mixture does not exceed the vapour pressure of ether at room temperature As this vapour pressure is

---

* See the fourth paper in this series

The apparatus requires no further attention until the temperature falls below t_1 This indicates that all the calcium chloride has been solidified and a further filling of hot water is now required The hotter the water added the less often is it necessary to refill If by any mistake hot water is added too frequently the mercury in the thermometer may rise above the danger mark t_2 If this happens *cold* water must be poured into W to prevent the ether from boiling

SUMMARY

In the Oxford Vaporiser No 1, a liquid anæsthetic, such as ether, is maintained at a constant temperature below its boiling-point, thus making available a constant supply of vapour The concentration of anæsthetic vapour in the inspired air is controlled by a calibrated mixing tap which determines how much of the inspired air passes through the vaporiser, and how much by-passes it

The principle of the vaporiser is that hot water is used to melt a crystalline " reservoir " substance, and then this molten substance yields up its latent heat of crystallisation to provide, as required, the latent heat of evaporation of a liquid anæsthetic , the reservoir substance remains at a constant temperature until it has all resumed the crystalline form For the vaporisation of ether, hydrated calcium chloride, which melts at 29° C , has been found suitable To maintain the vaporiser in operation it is necessary only to fill at intervals with ether, and with sufficient hot water to re-melt the crystals , cylinders of compressed gas are not required Since the machine delivers vapour only during inspiration it is economical in use Artificial ventilation, with or without anæsthetic vapour, can be administered by a spring-loaded bag

We are indebted to Mr A V Oak, chief engineer of Morris Motors Ltd , and his colleagues for many helpful suggestions, and for redesigning the vaporiser in a form suitable for production in large numbers

---

THE OXFORD VAPORISER NO. 2

S L Cowan, D SC LOND

R D Scott, M B DUBL

S F Suffolk, B SC LOND

Nuffield Department of Anæsthetics, University of Oxford

In the Oxford Vaporiser No 1 a liquid anæsthetic, such as ether, is maintained at a temperature below its boiling-point and the concentration of anæsthetic vapour in the patient's inspired air is controlled by means of a calibrated mixing tap, which determines the fraction of the inspired air passing over the liquid surface The Oxford Vaporiser No 2 has been developed to maintain a quantity of liquid anæsthetic at a temperature at which its vapour pressure exceeds atmospheric pressure—i e , above its boiling-point * The undiluted vapour can be obtained from a vessel containing an anæsthetic liquid in this condition, just as at room temperature gaseous nitrous oxide can be obtained from a cylinder of liquid nitrous oxide The rate of flow of the undiluted vapour is measured, and the vapour is then mixed with any other gas or gases desired Condensation must not be allowed to take place either during these operations or during the subsequent passage of the gas mixture to the patient

The latent heat of evaporation of the anæsthetic liquid is provided by the latent heat of crystallisation of a " reservoir " substance previously melted by hot water The reservoir substance is chosen so that the anæsthetic liquid is maintained at such a temperature as to produce a vapour pressure of less than one atmosphere above normal Thus the necessity of constructing a vessel to withstand high pressures is obviated We have endeavoured to make the heat transfer from the reservoir substance to the anæsthetic liquid sufficiently rapid to ensure an adequate supply of vapour (*a*) by constructing the dividing wall of metal of high thermal conductivity, and (*b*) by providing fins of similar metal which p from one vessel to the other

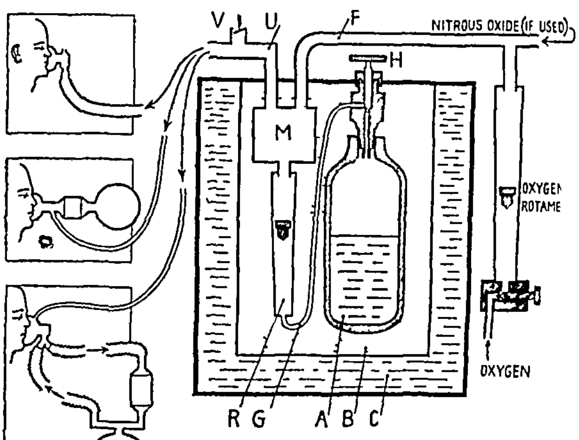

Fig 1—Diagrammatic vertical section throu Oxford Vaporiser No 2 A contains ana thetic, B crystals and C hot water F a G connecting tubes, H fine adjustment valv M mixing chamber, R flowmeter (" Rotameter "), U connecti tube, V inspiratory valve

DETAILS OF CONSTRUCTION

The most convenient arrangement of the compa ments was found to be in the form of three vessels, inside the other (fig 1) The anæsthetic liquid is c tained in the inner vessel A, the reservoir substance the intermediate B, and water in the outer vessel The inner vessel is a strong metal cylinder closed at e end, and will hold 12 fl oz of anæsthetic liquid Fin the same metal are inserted radially (fig 2) A fi adjustment needle valve H, situated on the top of cylinder controls the rate of outflow of the vapour prevent condensation the valve is immersed in reservoir substance so as to leave only the spindle a packing gland uncovered Although the pressure in vessel and valve should never reach one atmosphere ab normal they are tested to not less than ten atmosphe

The rate of flow of the vapour is measured by a fl meter of the rotating bobbin type R (" Rotameter ") prevent condensation of the vapour, the flowmeter to be warmed to at least the same temperature as anæsthetic liquid Moreover, the temperature of meter must be maintained constant in order to prev inaccuracies due to the changes in density and visco of the vapour, which would result from fluctuations temperature In order to achieve this constant tempe ture, the flowmeter is surrounded by a metal sleeve high thermal conductivity and several fins attached the sleeve pass deep into the reservoir substance T sleeve is fixed in the outer wall of the reservoir co partment At this point the water compartment interrupted, and a window Y cut in the metal sleeve expose the graduations on the meter and enable t position of the bobbin to be read (figs 2 and 3) T connecting metal tube G between the needle valve a the bottom of the flowmeter is also kept warm immersion in the reservoir substance

After leaving the flowmeter the anæsthetic vapo passes through a short tube to a mixing chamber where it mixes with oxygen, or any mixture of gas desired—e g , oxygen and nitrous oxide The rate of fl of each gas used is measured by passing it through a rot meter (see fig 3) before it enters the mixing chamber Th chamber is made of metal of high thermal conductivi and is immersed in the reservoir substance so that mixi takes place at a temperature which prevents condensati of the anæsthetic vapour Condensation can, howeve take place in the tubes connecting the apparatus the patient unless the precautions discussed below a observed Both in the tube F leading the oxygen or g mixture to the mixing chamber and in the tube U leadi to the patient a short length of tubing of low therm conductivity, such as a length of bakelite tubing, interposed This greatly reduces the loss of heat b conduction from the reservoir substance to the out parts of the apparatus

---

* S R Wilson and K B Pinson (*Lancet*, 1921, 1, 336) produced an apparatus similar to the one described here in that it consisted of a strong metal vessel which was filled with ether and then immersed in very hot water

4% has the same significance During the first two or three weeks of illness eosinophils usually comprise 15–40% of the total circulating leucocytes Great variation in the actual percentage is often noted from day to day Rarely it may be necessary to make more than one examination before the eosinophilia is demonstrated In people who are moribund or in whom there is a pyogenic complication such as pneumonia there may be a temporary suppression of these cells In most instances eosinophilia persists for at least 3 months after the beginning of an infestation, and disappears sometime before the end of 12 months

Immune reactions —After an infestation with *Trichinella spiralis* specific antibodies are developed by the host Their presence may be demonstrated by a skin test or by a precipitin test with trichinella antigen (Augustine and Theiler 1932) The antigen employed is a saline suspension of powdered larvæ of the parasite When good preparations of antigen have been employed a positive skin reaction has been obtained in over 90% of clinical cases (Bozicevich 1938) The reaction is relatively specific, false positive reactions are rare One feature which detracts somewhat from the value of of this test as a diagnostic aid is the fact that a positive response may be exhibited for several years after an infestation, consequently it cannot be interpreted as an indication of recent infestation In the United States routine skin tests on hospital patients have revealed positive reactions in as many as 10% of persons (McCoy, Miller and Friedlander 1933, Shapiro, Crosby and Sickler 1938) The skin test is of real value when a positive response is obtained in a person who had previously given a negative one, this being almost certain evidence of a recent infestation Furthermore, a negative response in a subject who has been ill for four weeks or longer is strong evidence against a diagnosis of trichiniasis

Skin test —0 1 c cm of a 1 in 10,000 dilution of antigen is injected into the skin of the forearm An equal amount of normal saline is injected 5 cm distally, as a control Two types of positive response have been described delayed and immediate The delayed type becomes evident after 12–24 hours It consists of redness and induration, and is similar to a positive tuberculin reaction This type of response may be elicited as early as the end of the second week of illness, but is usually present only for a few days, after which the response is of the immediate type (Spink 1937) The immediate reaction develops during the third or fourth week of illness, and can be elicited for many months, sometimes for years, after an infestation This usually consists of wheal and erythema, but in some instances erythema is the only evidence It appears within 10 minutes of the time of injection, and begins to fade after 15–20 min

Precipitin test —This may be employed when the response to an intradermal test has been equivocal The essential technique consists in adding undiluted blood-serum to an equal volume of antigen diluted 1 200 or 1 500, and incubating the mixture for an hour at 37° C The appearance of a precipitate indicates the presence of specific antibody Precipitins usually develop at about the same stage of the disease as that at which the intradermal reaction becomes positive

Widal reaction —The development of agglutinins for *Bacterium typhosum* during the acute stage of trichiniasis has been observed occasionally (Dammin 1941) This possibility must be borne in mind because trichiniasis can simulate typhoid fever clinically I have recently tested the sera of 15 people who had been ill with trichiniasis 2–4 months previously There was no significant elevation of agglutinins for either " H " or " O " antigen of *Bact typhosum* in any of those sera

X ray of muscle —There exists a misconception that calcified trichinella cysts can be identified by X-ray examination of muscles Actually these cysts are so small that they can seldom if ever be distinguished radiologically during life It is probable that some appearances which in the past have been interpreted as due to trichinella cysts (Gouldesbrough 1918) were in reality *Cysticercus cellulosæ* Gray (1939) quotes Kirklin in the statement that there is no record of trichiniasis having been recognised radiographically at the Mayo Clinic

SUMMARY

The clinical features of trichiniasis are discussed, attention being directed to the variability of the disease, both in the nature of its manifestations and in the severity in different individuals

An eosinophil count is the best guide to early diagnosis The parasites can sometimes be isolated from the blood during the early weeks of an infestation They can usually be found in muscle tissue after the third week The specific skin test and the precipitin reaction with trichinella antigen are useful diagnostic procedures under certain conditions

BLOOD-PICTURE IN TRICHINIASIS

B L DELLA VIDA,
M D ROME
ASSISTANT PATHOLOGIST

S C DYKE,
D M OXFD, F R C P
DIRECTOR, PATHOLOGICAL DEPARTMENT

THE ROYAL HOSPITAL, WOLVERHAMPTON

DURING the recent outbreak of trichiniasis in Wolverhampton reported by Sheldon (1941) we have through his kindness had the opportunity of observing the blood changes in about a hundred patients at various stages of the disease

Little systematic study seems to have been made of the blood changes in human beings suffering from this infestation The most complete is that of Brown (1898) but this related only to 1 case studied over three months and to 2 others followed for only a few weeks Much work has been done on the blood changes in infestations in the lower animals but the findings recorded show considerable variation, and their applicability to human infestation must be doubtful Maass (1933), in pigs, observed leucocytosis and an eosinophilia increasing steadily for twenty to twenty-four days after infestation and followed after a peak lasting one or two days by a steady fall to a normal figure Wantland (1937), working with rabbits, described a leucocytosis developing in the second week after infestation and an eosinophilia reaching a maximum of 25–79% appearing during the third week and thereafter persisting at a high level for several months McCoy (1932–33) found no definite eosinophilia in trichinosed monkeys Van Someren (1938), working with rats, found blood changes developing within four hours of infestation, these consisted of a neutrophilia with concomitant lymphopenia, the proportional distribution of the two types of white cells was fully established within two days from infestation and persisted for a considerable time, total counts of the white cells were not done The eosinophils decreased in the early stages of infestation, after about three days they began to increase and reached their maximum of 13–20% between seven and sixteen days later, the eosinophilia was found to fluctuate and two or more rises with intervening periods of low eosinophilia were observed, in heavily infested animals there was no increase in the eosinophil percentage, the cells remaining scanty or disappearing altogether, these animals invariably died within two weeks Beahm and Downs (1939) failed to find any significant eosinophilia in rats after experimental infestation

Brown in his 3 human subjects found a leucocytosis with absolute and relative increase in the number of eosinophils, the neutrophils showed a fall in total numbers and the lymphocytes a rise Brown noted the phenomenon, seen in our own cases, of primary and secondary waves of eosinophilia Three syndrome usually described as typical—gastro-intestinal symptoms, fever, œdema of the eyelids and muscle pain—is probably encountered only in severe forms of the disease Field studies indicate that some people who contract trichiniasis remain subjectively normal (Drake, Hawkes and Warren 1935), and that still more have a less severe and less distinctive illness, characterised by such symptoms as malaise, fatigue and backache Many people under such circumstances do not seek medical advice, and few physicians would suspect trichiniasis as the cause of symptoms so mild and so indefinite In addition to these milder cases, however, many examples of moderate or severe illness due to trichiniasis go unrecognised by physicians, partly because descriptions in medical textbooks often fail to emphasise significant features of the disease The following remarks are based on recent personal observations and on study of numerous case-reports

Incubation period —In the majority of instances symptoms first appear 7–12 days after ingestion of the parasite, but like all diseases of this class there may be considerable variation In one American outbreak, traced to a single meal, the onset of symptoms ranged from the third to the twentieth day (Ferenbaugh, Segal and Schulze 1938)

General manifestations —There is nearly always some rise of body temperature In most cases this does not exceed 102° F, but in exceptional instances a high sustained fever is present for many days There may be rigors The pulse-rate is usually increased in proportion to the fever

Integument —Œdema of the orbital tissues (sometimes extending to involve the whole upper portion of the face) is a very frequent manifestation Chemosis may be present, or there may be much suffusion of the conjunctival blood-vessels These signs develop during the first week of illness, and seldom persist for more than a few days Œdema of the extremities may be present, usually being associated with pain and tenderness in the underlying muscle groups Œdema over the sacrum or of the scrotal tissues is not usual Skin eruptions are uncommon, although various types of rash have been described morbilliform, urticarial or nodular Subungual hæmorrhage, which is especially likely to occur in severe cases, is a striking clinical sign and, almost pathognomonic The lesions are similar to the "splinter hæmorrhages" of subacute bacterial endocarditis, but are more extensive in trichiniasis, often forming a continuous line beneath the distal end of each finger nail (McNaught 1939)

Cardiovascular system —Hypotension is common during the febrile stage According to one case-report the blood-pressure fell to as low as 44/18 mm Hg (Cheney 1926) Electrocardiographic changes were noted in 6 of 18 patients studied at one hospital (Spink 1935) The changes were flattening or inversion of the T wave in lead 2, low amplitude of the QRS complex, and evidence of intraventricular block Pathological examination in fatal cases usually reveals an interstitial myocarditis, and larvæ have been found in the human myocardium, although they do not become encysted there Cardiac decompensation may be a manifestation of severe trichiniasis, but patients surviving the acute stage apparently have no permanent impairment of cardiac function

Nervous system —It has long been appreciated that lesions of the central nervous system may develop in trichiniasis, but the frequency and importance of these has not been stressed sufficiently When present they often dominate the clinical picture Sheldon (1941), in a careful study of 76 cases, noted neurological signs in thirteen patients These included focal pareses and signs of general inflammation, suggestive of meningitis or encephalitis In conjunction with such signs the cerebrospinal fluid may present no abnormality, or there may be pleocytosis and increased protein content Kaufman (1940) calls attention to the frequent coexistence of signs of encephalitis and myocarditis This may be ascribed to the fact that these two conditions are features of heavy infestations, where it is reasonable to assume that many parasites have been deposited in both brain and heart

Gastro-intestinal system —Such symptoms as abdominal pain, distension, diarrhœa or constipation occur in less than half the clinical cases of trichiniasis They usually subside within the first week of illness, although in rare instances abdominal pain may persist for several weeks Blood or mucus in the stools is not characteristic of trichiniasis, a point which is sometimes useful in the differentiation from dysentery

Respiratory system —There is too little recognition of the fact that cough and pain in the chest are frequent symptoms of trichiniasis Cough is probably caused by the presence of parasites in the lungs It is non-productive in most cases, although hæmoptysis occurs occasionally The chest pain may be attributed to infestation of the intercostal muscles or the diaphragm

Lymphatic system —Enlargement of the spleen is fairly commonly noted Swelling of the lymph-nodes has been described, but is rare

Fatality —Cases that terminate fatally usually show evidence of myocarditis or encephalitis or both Pneumonia may be a contributing cause of death The fatality in recent epidemics has been less than 5% If subclinical infestations are included the rate is probably less than 1%, and in the later English epidemics the fatality among cases notified was not more than 1%

Sequelæ —Complete recovery is the rule, though exceptionally there may be a permanent paralysis Some muscular pain or stiffness often persists for several months after a severe infection but progressive improvement usually takes place In a follow-up study of 70 patients, Bercovitz (1940) found that none of the patients had symptoms a year after the acute illness

Differential diagnosis —More frequent recognition of clinical trichiniasis will result only when doctors become more alert to the many possible variations of the disease Trichiniasis taking the form of a febrile illness without localising signs may resemble influenza or typhoid fever Respiratory symptoms may lead to a diagnosis of bronchitis, pleurisy or pneumonia Neurological lesions may produce the signs of meningitis, encephalitis or cerebral vascular accident Gastro-intestinal symptoms may cause confusion with dysentery or food-poisoning The orbital œdema resembles that of acute nephritis or sinusitis A practical example of possible errors was cited by Otto and Janney (1937) who reported an episode in which the following clinical diagnoses were made on seven cases of trichiniasis occurring in one family influenza, mumps, encephalitis, typhoid fever and acute alcoholism

DIAGNOSTIC PROCEDURES

Demonstration of the parasite —Although adult trichinellæ are excreted in the fæces during the first few weeks of an infestation, they are not easy to find, and search for them is usually a waste of time On the other hand, larvæ can sometimes be found in the blood during the first three or four weeks This means of diagnosis should be used more frequently, the technique is simple and does not require experience Whole blood is laked by diluting 5 c cm with 10 volumes of water This mixture is centrifuged and the sediment is examined under low power magnification The size of circulating larvæ is approximately 100 μ by 6 μ, their bodies have a granular appearance Larvæ have been found in the cerebrospinal fluid, but not in urine After the third week of illness biopsy of voluntary muscle is a fairly certain means of finding the parasites They are usually more numerous in certain muscles, such as diaphragm, intercostals and masseters, a circumstance which may be related to the glycogen content of different muscles (Lewis 1928) Because of accessibility the muscles usually chosen for biopsy are the deltoid or gastrocnemius Approximately 1 gramme of tissue is excised One portion of it can be examined immediately, pressing the tissue between two glass slides and searching for parasites, using low-power magnification The remainder can be sectioned and stained in the usual way, and examined for parasites or evidence of myositis

Eosinophilia —The differential leucocyte-count is the best guide to early diagnosis Relative and absolute increase in eosinophils is an almost constant accompaniment of the stage of larval dissemination If the total leucocyte-count is more than 10,000 per c mm of blood an eosinophil count of more than 400 may be interpreted as an eosinophilia If the total leucocyte count is less than 10,000, a proportion of eosinophils greater than

(B L D V) was able with the clinical symptoms in view to make a diagnosis of trichiniasis on the strength of the presence of these acidophil neutrophils in all the typical eosinophilia appeared later These acidophilic granules of the neutrophils were somewhat smaller than those of the true eosinophil cells but slightly larger than the neutrophil granules they varied greatly in number in the cytoplasm of individual cells even in the same film , in some they were scanty, in others so numerous as to make differentiation from a true eosinophil a matter of considerable difficulty

The absence or paucity of eosinophils in the earliest stages of infestation has been ascribed by various authors to the fixation of the eosinophils present in the blood-stream around the adult worms as they embed themselves in the intestinal mucosa Later, in response to the toxins liberated by the worms the bone-marrow secretes and mobilises more of these cells and the percentage in the blood-stream increases This brings about the first wave of eosinophilia From the fifth to the seventh week after infestation the larvæ are migrating to and establishing themselves in the striated muscle , again there is a fixation of eosinophils around the encysting worms which accounts for the decline in the eosinophils found from the fifth to the seventh week after infestation and preceding the second and final wave of eosinophilia

All the cases we saw showed some degree of eosinophilia after the first three days, and all recovered A persistent absence or low level of eosinophils in the blood-stream is said to be of bad prognostic significance in trichiniasis Spink (1934) however, observed that animals experimentally infested with trichinella failed to develop an eosinophilia when they had a bacterial infection as well , this finding may also apply to human beings and if so would have to be taken into account in diagnosis

SUMMARY

The blood-picture has been followed in about 100 patients suffering from infestation with *Trichinella spiralis* The following points were observed

Leucocytosis occurs in a primary wave reaching its peak at about the third week from onset of symptoms and a secondary wave reaching its peak at the eleventh week

The eosinophils diminish or may disappear within the first three days from onset of symptoms ; thereafter they increase in primary and secondary waves coinciding with those of the general leucocytosis

The neutrophils diminish during the waves of general leucocytosis and increase as the eosinophilia diminishes

The monocytes increase with the first diminution in the eosinophilia

In addition to true eosinophil cells neutrophils bearing within their cytoplasm greater or lesser numbers of eosinophilic (acidophilic) granules may appear especially in the early stages of infestation

Our thanks are due to Dr J H Sheldon for access to case-histories

ELECTRICAL CONVULSION THERAPY

A M Wyllie, M D Glasg , D Psych
MAJOR, R A M C DEPUTY PHYSICIAN SUPERINTENDENT OF CRICHTON ROYAL MENTAL HOSPITAL, DUMFRIES

The method of producing convulsions by electrical stimulation introduced by Cerletti and Bini in Rome has been used in this country by Shepley and McGregor (1939, 1940), and by Fleming, Golla and Grey Walter (1939, 1940) In this hospital we have used the simple and inexpensive machine devised by Grey Walter When this is used in a favourable case there is an immediate spasm of the muscles on pressing the shock button The thighs are flexed on the abdomen, the arms are extended, and the facial muscles produce a grimace A few seconds later the true tonic spasm sets in, often heralded by a cry and fixed staring eyes, with conjugate deviation to one or other side The tonic spasm is essentially the same as that induced by Cardiazol, but it is a little shorter in duration and less powerful The veins of the head and neck stand out prominently and the skin is red and congested while the eyelids close spasmodically The mouth which is open at the beginning of the tonic stage closes powerfully and there is a tendency to bite the tongue Carpopedal spasm follows with hyperextension of the fingers, and the arms are extended while the legs are flexed on the abdomen Towards the end of the tonic stage the legs are fully extended " Goose-flesh " is often present The clonic stage follows and the colour becomes livid When the clonic jerkings settle down, respiration is spontaneously re-established, there is a short period of hyperpnœa, and the patient quietly returns to consciousness This description belongs to the majority of cases, but each patient has his own individual reaction A few of my patients were extremely restless and difficult to control for 5–10 minutes after the fit In many cases it was necessary gradually to increase the impulse in intensity and duration as the course progressed in order to secure a complete reaction Treatments are given thrice weekly at first, then twice weekly, according to the patient's progress

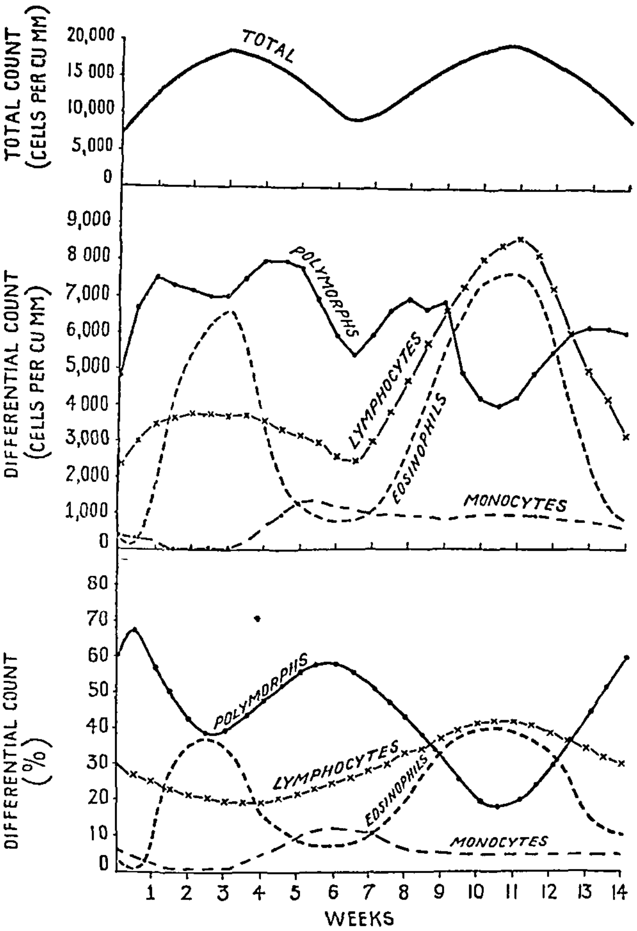
It has been claimed for this treatment that the amnesia is complete and fear of treatment consequently eliminated In my experience the amnesia is deeper than with cardiazol or triazol but fear is not eliminated although it is diminished Most patients who were sufficiently intelligent to express an opinion disliked the treatment , some hated the " going off " and others the " coming round " Nevertheless, appreciating their own rapid improvement most of them were fully coöperative One patient who had triazol shortly after a course of electrical shocks referred to electrical therapy as " the nice treatment " and triazol as " the bad treatment " Some of the schizophrenic patients resisted being brought for treatment—partly from general negativism —and so did some resistive melancholic patients Among the melancholics, however, it was noticeable that resistiveness diminished as the treatment progressed and the patient improved

The patients recovered quickly from the fit and after a period of confusion lasting 10–30 minutes were able to be up and moving about Many complained of headache on the evening after treatment and a few vomited Muscular pains—a constant feature of cardiazol and triazol therapy—were rarely complained of only three patients being affected in this way No fractures or dislocations occurred in this series but among patients since treated there was one compression fracture of the spine and one dislocated shoulder

In nearly all cases amnesia was complete for a period lasting from a few seconds before the impulse till 5–10 minutes afterwards Even when a major convulsion was not produced amnesia was complete—an important difference from cardiazol and triazol therapy An ineffective injection of these drugs often causes fear and apprehension and produces resistance to treatment , failure to produce a major convulsion by the electrical method does not in any way prejudice the continuance of the treatment After an incomplete reaction the patient recovers quickly and can walk away from the treatment couch Several patients complained of disorder of memory distinct from the amnesia covering the period of the treatment There was a transient retrograde amnesia of a patchy type and a retention defect , these memory symptoms were more severe than those following cardiazol or triazol therapy

RESULTS

Twelve cases of involutional melancholia were treated three recovered and were discharged , two recovered and are convalescent, one of these being a woman of 56 who had been ill for more than 12 months, and the other a woman aged 59 who had been ill for more than 2 years Six chronic cases showed improvement and another case improved but relapsed This recovery-rate cannot be fairly compared with the spontaneous recovery-rate, weeks from the onset of symptoms he found the eosinophilia to attain its first peak, the highest figure recorded being 37%; thereafter it declined to a level of 8–15% at which it stayed for about two weeks; a secondary rise in the eosinophils then began which attained its maximum in about four weeks, the highest figure observed being 68%; from this peak there was a gradual decline in the eosinophil percentage, the last observation—made eighty-five days after the onset of symptoms—giving a figure of 16%. Many observers have reported increase of eosinophils in human trichiniasis, but with the exception of Carter (1930) none seems to have followed the blood changes over any considerable period. Carter observed 2 subjects over two years and in one found the primary and secondary waves of eosinophilia as seen by Brown and ourselves.



Composite blood picture compiled from observations in 100 cases of trichiniasis. Time is taken from the appearance of swelling of the eyelids.

In 4 only of our cases was the diagnosis of trichiniasis confirmed by biopsy. We had no antigen for skin-testing, so that in all other cases of the series the diagnosis rested on the blood-picture and clinical appearances. The clinical picture, as pointed out by Sheldon, was clear and unmistakable and there was no doubt as to the correctness of the diagnosis in all the cases included. Some cases were followed for a considerable time and blood examinations made at regular intervals; in others only one examination was made. In all cases full clinical histories were available and it has therefore been possible to construct a composite picture of the blood changes occurring in the human subject throughout the first few months from infestation.

It was not always possible to make a total count of the white cells; our own results however and the study of those of others lead us to believe that the percentage distribution of the white cells in these cases roughly follows variations in total numbers. In epidemics of this sort the majority of the patients are usually seen outside hospital, and only a blood-film is available for examination; diagnosis therefore has to be made on the percentage figures. In examining films, Jenner's stain, which gives good differentiation between the types of cytoplasmic granules, was used. In making differential counts 100 cells were always, and 200 usually examined. For purposes of charting, the day of disease was calculated as from the date of the appearance of the symptom common to all cases—swelling of the eyelids.

ANALYSIS OF RESULTS

A leucocytosis appeared immediately after the appearance of symptoms; this might reach a level of 30,000 white cells per c mm, but more usual figures were between 12,000 and 15,000 (see figure). The initial leucocytosis persisted for three or four weeks, after which it declined to a more or less normal figure at about the sixth week. Thereafter a second rise in the total number of leucocytes occurred attaining a maximum at about the eleventh week from the appearance of symptoms; this was followed by a slow decline to normal.

The number of the eosinophils closely followed the rise and fall in the white-cell count. In the first three or four days of illness there was no appreciable eosinophilia—in some cases no eosinophils at all could be seen in the films; a similar aneosinophilia was noted by Van Someren in rats. About a week from the onset of symptoms the eosinophil count began to rise, and quickly reached 20%–50% or even more; the highest figure observed in the present series was 71%. After this first peak the eosinophils decreased, both totally and relatively, and at the end of the fourth week reached figures of 5%–15%; at this low level they remained for from three to four weeks after which the secondary rise commenced. The peak of the second wave was attained in about ten weeks from infestation; this was followed by a gradual decline, but a low grade of eosinophilia was still found some months later.

The neutrophils followed a course inverse to that of the eosinophils, their percentage decreasing with the first wave of eosinophilia, increasing as the eosinophilia decreased, and then falling again with the start of the second wave of eosinophilia.

The lymphocytes were diminished or present in normal numbers during the first stage of the infestation; a noticeable increase began at about the fifth week and lasted up to the eleventh or twelfth week, after which there was a decline to a normal figure.

Some authors have stated that the monocytes and basophils show no variations in numbers either relative or absolute in human trichiniasis. Many of our cases during the first few weeks of infestation showed diminution, sometimes resulting in complete disappearance of both types of cells. At the time of the fall of the eosinophils in the fourth to seventh week the monocytes returned to a normal or even higher level. The basophils attained a normal level a little later.

MORPHOLOGY

The morphology of the lymphocytes, monocytes and basophils showed no departure from normal throughout the course of the infestation. The eosinophils were usually of the ordinary type, slightly larger than the neutrophils and showing with Jenner's stain coarse eosinophilic granules. The nuclei were usually bilobed but in some cases many cells with three or more nuclear lobes were noted; in one case a small proportion of eosinophilic metamyelocytes was seen. Many films showed "shadow" eosinophils represented only by a cluster of eosinophil granules liberated from a disrupted cell. The appearance of these seemed to be of no particular significance.

In the later stages of the infestation the neutrophils presented the usual appearance. In the early stages, however, many of them showed in the cytoplasm, along with the typical neutrophilic, a greater or lesser number of eosinophilic granules. This type of cell was observed by Brown in muscle obtained by biopsy from his patients and led him to suggest that the eosinophils found in the blood-stream were actually derived from neutrophils. This conclusion is hardly in accord with present views on the genesis of the white cells; whether it be correct or not it is a fact that in a number of our cases this acidophilic change in the neutrophils showed itself before any excess of true eosinophils appeared in the blood-stream. In several very early cases one of us

TAMING THE ANÆSTHETIC

ETHER is admittedly the best general anæsthetic we have It is less toxic for the patient than any other liquid anæsthetic, and it is relatively cheap and easy to handle But it suffers from two drawbacks One is chemical and unavoidable Its inflammability and low flash-point make constant vigilance the price of safety and forbid the use of many forms of electrical apparatus The other, which is physical, is shared with every other liquid that has to be vaporised before it can be used A great deal of heat is required for the conversion from liquid to vapour and how to supply this heat has taxed the ingenuity of every anæsthetist since ether was introduced The rough and ready way was to let the patient's breath do the warming, whether by mere conduction or by the heat liberated in condensing its water vapour In the process both anæsthetic and apparatus were apt to get chilled and in practice an even flow of warm, accurately dosed ether vapour was never reached A flash of genius in seeing the obvious has now solved this difficulty at the Nuffield department of anæsthetics, Oxford, where they have set a thief to catch a thief If at 34° C ether mops up no end of heat for the change from liquid to vapour, at a degree or two lower (say 30° C) melted crystals of calcium chloride will provide a reservoir of heat at a constant temperature on their change from liquid to solid Place the crystals between the hot water and the ether and the heat will get through all right, but only at precisely the required level, neither too hot nor too cold To vaporise 15 fluid ounces of ether in an hour requires no more than a kilo of crystals and a jug or two of hot water How the end was reached and the constructional difficulties overcome will be read with keen enjoyment by everyone who appreciates the adaptation of simple means o a harmonious end

Now that ether vapour can be handled as freely as itrous oxide, its concentration measured and dosed t will, and the vapour mixed in any desired propor-ion with oxygen or other gas, ether may reveal hitherto unsuspected virtue as an anæsthetic The Oxford vaporisers will make it easy to explore the ighter planes of anæsthesia which were difficult to maintain with the older methods Anæsthesia at these levels is particularly desirable in shocked patients and for that reason ether has been widely discarded n the emergency operating room Tamed by the new method it may do better when given another trial In the laboratory too the vaporisers will be very welcome, for they will enable the experimental physiologist to gather accurate data about narcosis in animals There is a growing appreciation of the importance of depth of anæsthesia, and the application of laboratory findings will supplement and enrich clinical experience Happily there need not in this instance be the usual lag between scientific conception and delivery The vaporisers have had the most scrupulous antenatal care and engineering craftsmanship of the highest order is attending their birth

OVERDUE LEGISLATION

THE Pharmacy and Medicines Bill gives our legislators the chance to do a greater service to the nation's health than they have achieved for many a year For reasons not invariably creditable to the democratic system of law-making, previous opportunities of controlling the predatory advertisement of quackery have been neglected Select committees have patiently examined evidence and have put forward recommendations, bills have been promoted, but overdue reforms have been thwarted either by the apathy of the M P or by the alertness of vested interests Even a *postmaster-general* has refused to censor the advertisements carried in his books of stamps, national health meant less to him than revenue Even now the Pharmacy and Medicines Bill, though sponsored by the Minister of Health, owes its genesis and impetus to fiscal considerations It is the aftermath of a finance bill Successive chancellors of the exchequer have become conscious that the medicine stamp duties are anomalous and anachronistic, that litigation might at any moment reveal fatal irregularities in the collection of the tax and, in short, that the repeal of the duties cannot be delayed The loss to the Exchequer would be some £840,000 per annum, but at present the application of the purchase tax to medicines is likely to bring in more than three times as much Our administrators cannot fail to be aware of the fantastic incidence of these ancient medicine duties which the High Court has described as a mass of confused and obsolete verbiage "Cough mixture" is taxable, "chest mixture" is not, "backache and kidney pills" are taxable, "back and kidney pills" are not It is not the fiscal or administrative aspects which interest the medicine-buying public or the medical profession Lord HORDER put the point significantly a few years ago when he said that, for every hundred pounds spent by the government in making people health-conscious, the quack medicine-mongers were spending a thousand in making them medicine-conscious In the words used by the Minister of Health in introducing the bill on July 8, opportunities still exist for the unscrupulous to trade upon the credulity and fears of the ill-informed by the production of useless (or even harmful) secret preparations, and to delay the seeking of proper advice and prompt treatment for serious diseases by advertising quack remedies Existing laws check advertisements of cures for venereal disease and cancer The Government's bill proposes to extend this restriction to Bright's disease, cataract, diabetes, epilepsy, glaucoma, locomotor ataxy, paralysis and tuberculosis This is nearly the same list as in the Duckworth Bill of 1936, though it omits the 1936 proposals for a further extension to cures for amenorrhœa, hernia, blindness and structural or organic ailments of the auditory system The new bill also proposes, as did the bill of 1936, to forbid advertisements relating to abortion The restrictions now put forward go no further than the code of advertising standards already voluntarily adopted, to its great credit, by the Proprietary Association of Great Britain Other features of the bill speak for themselves—a justifiable improvement of the pharmacists' position, a balanced agreement between vendors who are chemists and those who are not, and an important clause to compel he collapsed at his work His doctor treated him for "the gastric" Under evipan hypnosis he re-experienced fears, tremblings, stomach discomfort Said he wanted to fight against it and be like other men but had not succeeded He gradually regained his self confidence and was discharged recovered

CASE 10 —A woman of 52 Seven bombs were dropped within a radius of 1000 yards, the nearest being about 10 yards from her, it took off part of roof of shelter and blocked the exit On admission she complained of a nasty blankness over her head, and said she could not think of anything, and could not seem to speak like other people Constantly heard German aeroplane noises She looked depressed and some what agitated She stated that she had always been a cheerful personality and that the air raids did not worry her She remembers being thrown to the ground when a bomb exploded near, and though dazed she managed after an interval to walk home with help She is regarded as a case of "blast shock" She has made steady improvement and has been discharged as recovered

CASE 11 —A woman of 35 who complained of "nervousness due to raids" She dreaded the raids and suffered from sleeplessness, diarrhœa, frequency of micturition and head aches Physical examination revealed no abnormality except some tachycardia No emotional conflicts were revealed after an intravenous injection of evipan Her illness is a simple fear reaction and after the mechanism of the symptoms was explained to her she ceased worrying She has lost most of the symptoms, though some headache still persists It is hoped to discharge her in the near future

CASE 12 —A man of 34 A case of concussion from effects of blast Had never been "nervy" until 5 months ago, when a landmine exploded about 100 yards away He was thrown to the ground and lost consciousness for a time There was slight hæmorrhage from the ears for 3 days and he developed severe headaches No fracture was detected by X ray examination No emotional conflicts were elicited after an injection of evipan, and he appeared to have been well adapted maritally and socially He now exhibits a post concussion syndrome, complaining of sleeplessness, severe headaches, giddy sensations, throbbing of the temples and difficulty in concentration

CONCLUSION

In 46 (15 3%) of 300 consecutive admissions air-raids were given as an ætiological factor, but in only 4 (1 3%) was this regarded as having a major influence, and in only 6 (2%) as contributory Of those in which air-raids appeared to be largely responsible for symptoms, 2 have recovered and 1 is much improved Of the 6 in which air-raids are thought to have been contributory, 2 have recovered and 2 have been discharged much improved It is therefore not expected that there will be any burden on mental hospital beds as a result of raids

I wish to thank Dr C J Thomas, principal medical adviser in psychiatry to the county of Southampton, for permission to make use of the hospital records

Reviews of Books

Human Biology

By G A BAITSELL, professor of biology, Yale University London McGraw Hill Publishing Company Pp 621 26*s*

THIS textbook suggests that the teaching of biology in American universities is less bound by outworn traditions than it is in our own It is time we considered whether the concept of evolution—which in the late nineteenth century was rightly the driving force of biological teaching but which is now no longer a live issue—should remain the foundation of biological education The average student would never discover the importance of modern biology for human life and thought unless in his spare time he turned from his textbooks to more popular scientific literature not usually recommended by his teachers Professor Baitsell remarks in his preface that most students beginning biology are more interested in the human than in any other living species "If the human biological material is presented from a comparative standpoint," he says, "the student will learn not only the biology of man, but also biology in its broader aspects, for man is a part of, not apart from, the world of life" In the average zoology course in our universities the existence of the human species is hardly mentioned, still more rarely is there discussion of his place in the economy of nature

Professor Baitsell's book is an introduction to animal physiology and anatomy, illustrated mainly by man, but dealing also with the physiology of plants and micro-organisms It is perhaps a pity that the physiology is presented entirely in the classical analytical manner, by separate functions, with no discussion of the biology of the organism as a whole which has practical application in hygiene, and the biological foundations of agriculture might have been more specifically discussed with advantage But in other sections of the book and in dealing with heredity and with the biology of disease, the writer contrives to keep the human relevance of his subjects always before his reader's mind

The Scientific Photographer

By A S C LAWRENCE, Ph D London Cambridge University Press Pp 180 18*s*

IN his preface Dr Lawrence points out that results of great value have been obtained in scientific work by using the photographic plate as a detector of new radiations, but that the photographic technique is still rudimentary, full use of photography is not made in laboratories, and many possess no photographic equipment and no member of the staff with technical knowledge This is true, methods of photography practised by the average amateur are not good enough for serious purposes Whether this book goes far to bridge the gap is perhaps doubtful but it does draw attention to the facts It makes no effort to be a textbook—there are other, more pretentious, works dealing with the technicalities of photography—but it does draw attention to applications that are often disregarded The early chapters deal with photographic processes and optics Dr Lawrence points out that the aperture of a lens is not a complete guide to its rapidity, and gives examples of other factors affecting it Writing of miniature cameras, he holds on good grounds that no negative should be so small as to need the use of a fine-grain developer

Chapters on colour photography and on developing and printing are useful The last chapter should be the most telling for it deals with some of the scientific applications of photography, but it covers too much ground, so that each subject is too cursorily treated Even so, this work as a whole is stimulating and indicates how laboratory work could with benefit be raised to a higher plane

Food The Deciding Factor

By FRANK WOKES, Ph D Lond, B Sc Lpool, F I C, Ph C London Allen Lane Pp 144 6*d*

THIS Penguin Special is addressed to the general British public Its aim is to explain the principles of nutrition so that everyone can take steps to get the right food and "help to bring victory nearer" The title is challenging and admirable and can be recommended, with the book, to the Admiralty, the War Office and the Ministry of Food, the Board of Education and the Ministry of Agriculture ought to read it too The tables in the appendices are useful, though it seems hardly necessary to include cockles, whelks and winkles in so small a book as this The advice given is up to date as far as possible though the book probably went to press before cheese was rationed—one cheese savoury needs 6 oz cheese, a month and a half's ration, but this sort of thing is inevitable when conditions change so rapidly Dr Wokes repeatedly reminds readers of the important fact that the phytic acid of whole cereals and some vegetables renders their calcium less available, and perhaps the tables in the appendices will convince his brother vegetarians that some of their sweeping statements about the mineral value of wholemeal bread are not founded on fact It is a pity that diet is presented from the chemical and biochemical standpoint, the jargon of these sciences simply obscures information for the layman he will buy a copy, try to read it, give it up and probably attach himself immovably to some point which he will magnify out of all recognition, ignoring the sound stuff behind the calories None the less, the book deserves a wide circulation, especially among those who are inclined to be cranky about diet slightest movement may tear young and tender healing tissues, and BARNES and TRUETA[3] have shown in animals how immobilisation controls the absorption of both bacteria and toxins Only in the case of the fingers where the stagnating lymph glues the small joints, is early movement required Of other joints OGILVIE[4] has written that ' early movement is as unsound as the early movement of fractures HUDSON has used the envelope plus hypochlorite method in 60 cases including burns ulcers and gangrene severe lacerated wounds and acute pyogenic lesions of the hands and elsewhere In all of his cases where sepsis might be expected the sulphonamides were used as well, and it is not easy to assess how much credit must go to them HUDSON regards this as a valuable addition to the surgeon s armamentarium though not as a competitor The full possibilities of this new form of an old weapon have yet to be explored and its applications in the treatment of wounds may turn out to be limited In the treatment of burns for which it was designed and especially those of the hands and face where early skin-grafting is particularly desirable it is likely to find its greatest use What it needs now as HUDSON says is care and thought · and unbiased thought at that

KEEPING COOL

MAN and the horse have the advantage over most animals in owning skins which act on the same principle as a butter-cooler and a very effective principle it is if the air is dry LEE[5] quotes an eighteenth-century experiment in which a healthy man, accompanied by a raw beef-steak, submitted himself to a dry atmosphere at 250° F and was all right at the end of a quarter of an hour while the steak was nicely done in 13 minutes On the other hand two brothers recently described by SUNDERMAN[6] in whom sweat glands were congenitally absent must give up work in summer, sleep on a cellar floor and go about in wet clothing LEE has studied man's reactions to hot climates in Britain, Singapore and Australia and he concludes that four types of crisis are possible when conditions overpower the body's normal mechanisms of skin adjustment hyperpyrexia (true heat stroke) circulatory insufficiency (heat prostration) · electrolyte imbalance (associated with cramps) · and hyperdehydration. Clinical cases rarely exhibit one syndrome exclusively though they can often be assigned to a single category from the majority of their signs Immediate passive adaptations do little to protect a man against prolonged heat a rise in the temperature of the skin and lung surfaces increases the rate of heat loss and promotes the evaporation of surface moisture Primary active adaptation includes cutaneous vasodilatation sweating, and water shifts with dilution of the blood The significance of the blood dilution is not clear, but with the sudden vasodilatation the capacity of the circulation is increased and the extra blood-volume helps to maintain circulatory efficiency and enables the body to get full value out of the vasodilatation If the primary measures fail the body is driven to secondary adaptive mechanisms, of which there are five . rise of body temperature, increased pulmonary ventilation reduced appetite alteration of endocrine balance and reduced muscular activity If these are not successful in maintaining thermal equilibrium disturbances of the cardiovascular system of acid-base and water and electrolyte balance and of the nervous system may develop providing stepping stones to failure of adjustment DREOSTI finds[7] that natives working in the Rand gold-mines are liable to either syncope or heat-stroke unless they are carefully acclimatised to full work in the deeper parts of the mine New workers are given light work underground for a week or more and are only allowed to take on full work when adaptation is complete Such adaptation can only be achieved, it seems by letting the man start work in a relatively hot place and gradually increasing his output which on the first day should be almost nil Natives who go home to their villages for six months on extended leave must be freshly acclimatised on their return The time taken by different subjects to adapt to full working conditions varies, and on the City Deep mine a heat chamber has been fitted up in which the powers of adaptation of new workers can be estimated under controlled conditions of work and atmospheric environment Among DREOSTI S cases the first symptom of heat-stroke was often maniacal excitement at the onset sweating ceased and was absent throughout the acute stage of the condition only returning when and if, recovery began.

Protective measures taken against heat must vary with the type of climate—a point which has perhaps received too little attention in the past The native inhabitants as LEE indicates, have usually solved their problem successfully and empirically The Arab, in a hot dry climate wears thick loose robes which shield him from radiation and set up mild convection currents whenever he moves , his houses are thick-walled and small-windowed, built about a central courtyard and all openings are kept shuttered until evening The Polynesian, living in moist heat, wears scanty clothing which cannot obstruct the evaporation of sweat into the almost saturated air, and builds his houses of lath and thatch lightly and airily. Only the European tries to rise above these obvious considerations and builds identical hotels in dry and wet tropical lands The ingrained conviction that the west must know best was illustrated when Florence Nightingale wanted all Indian hospitals to have widely opened windows It took the united voices of all the doctors in India and finally the command of the Viceroy to make it clear to her that the patients would be cooler with the windows shut Foil surfaces, as CROWDEN has shown,[8] can be used to reflect radiation whether used in the construction of houses or of solar topees topees lined with aluminium foil are now being worn by our troops in the east, and portable cubicles insulated in the same way and supplied with air-conditioning plants are also in use LEE discusses the effect of the screening of doors and windows against mosquitoes and concludes that in hot dry climates the interference with air movement occasioned by such screens is not detrimental but that it is a decided disadvantage in hot wet countries unless profuse sweating is taking disclosure of the ingredients of medicine sold by retail

Thunder comes up without warning, and many may have been surprised when a leading article in a great daily newspaper thundered against the bill on the morning of its second reading Reform, we were led to infer, was inopportune in war-time It seemed to be forgotten that the parallel restriction on advertising cures for venereal diseases was enacted in 1917, that valuable legislation for controlling the sale and possession of narcotic drugs (placed permanently on the statute-book in 1920) had first been initiated by defence of the realm regulations during the last war A great sum, which has been put as high as thirty million pounds, is spent yearly on self-medication , might not some of this be usefully diverted into war-time savings ? The bill, we were told, is an example of legislation based on decisions taken without full consideration of their consequences This criticism seems to suggest that the Select Committee on Patent Medicines never " reported " in 1914, nor the Select Committee on Medicine Stamp Duties in 1937, that the Government gave no pledge in 1934 to carry out the sensible agreement then reached between the cooperative societies and similar bodies, the chemists and the Home Office, that Sir Norman Birkett's strong committee never urged in 1939 the suppression of advertisements of articles for procuring abortion, and that neither House of Parliament has ever been addressed on the topic of the quack medicine trade Everything in fact is well if only it be left alone Fortunately the thunder passed over almost unheeded The bill received its second reading without a division Some minor amendment in committee is inevitable, but we hope and believe that Parliament will not fail to pass this useful measure into law

LAVAGE RETURNS

" I now come to Carrel's procedure of intercalating between the complete dressings a frequent flushing and refreshing of the wound surface and for carrying out this flushing unlaboriously Allow me to say that we have here, I think, far the most important contribution made to surgical technique since the beginning of the war But to that let me add, that while Carrel's precedure gives us a new and improved technique for the application of antiseptics, much more does it give us a new and improved technique for physiological treatment For that treatment the assiduous removal of corrupted and corruptible discharges is, as you know, the primary desideratum "—Sir Almroth Wright The Lancet, 1917, 1, 948

When this was written Carrel's method of treating infected wounds by intermittent lavage with Dakin's fluid had proved its value, and in the two years since its perfection at Compiegne had established itself as a routine in the Allied war hospitals Wright supported it not so much because of the antiseptic action of Dakin's fluid, as because, while removing dead material from the wound, it allowed the full antibacterial and digestive effects of the exudates to act during the intervals between irrigations Though the method marked a great advance, in the last two years of that war Baer and Winnett Orr, and to some extent Ogilvie and others, were already using the closed-plaster method which was based on almost a completely opposite principle Here the main accent was on the support and rest of healing tissues, and the organisms were let alone It was left to Trueta in the Spanish War to raise closed plaster from the fancy of a few to an unopposed favourite Nothing that has happened in this war has lessened its reputation from every casualty hospital have come glowing reports of its value—of the saving of life and limb, the smooth painless convalescence, and the little nursing required We have become as attuned to pus as the surgeons of the pre-Listerian era, and like them have accepted Matas's remark that " not all cheese that smells bad is bad " Lately we have seen even Trueta's results surpassed where his methods are combined with the local and general use of the sulphonamides

After such triumphs no-one would have foreseen a swing-back to lavage, and yet there are signs of one Bunyan and Vaughan Hudson and others[1] have lately described and reported on a method of enclosing wounds in specially treated silk envelopes to permit of lavage with a solution of hypochlorite made by the electrolysis of salt water As in Carrel's method the irrigation is intermittent Carrel advised some 20 douches a day , Bunyan in general gives 3 Bunyan claims that electrolytic sodium hypochlorite has advantages over Dakin's solution, being less irritant because it contains no free caustic soda, more constant in composition, and more effective because it contains ozone These claims seem in his paper to be unsupported, and it is unfortunate that many of the other desirable features possessed by any therapeutic solution of hypochlorite should here be ascribed to the electrolytic solution only Nothing but a controlled series, either human or animal, can decide whether Dakin's solution and eusol must really be counted back numbers, and the unbeliever may demand more evidence than Hannay gives us of the inferiority of saline All this must be for further inquiry It does seem certain however that, like Carrel, Bunyan has hit upon a highly convenient way of carrying out his irrigations With the technical assistance of Mr William Stannard he has evolved a treated silk fabric which can be made to fit over the wounded part, the edges being stuck to the skin so as to form an airtight joint Thus for a wound of the hand the whole hand is enclosed in the envelope, whose edge is attached half way up the forearm There is then no need for dressings between irrigations—indeed the progress of the wound can be kept under constant observation—and yet as long as the envelope is intact there is no risk of contamination from outside Even where irrigation is not required Vaughan Hudson finds the silk envelopes often a convenient and adequate cover for a wound

The new method has so far been used for some six months, and it is perhaps premature to say, as Bunyan does, that the problem of secondary infection will not now arise, and that catastrophes seen heretofore cannot now occur, though the 5 illustrative cases he describes are sufficiently encouraging He is unfair when he says of war surgery that some of the therapeutic advance up to date has been of an empirical, trial and error type, for in this war new methods have been remarkably carefully checked by experimental and other animal work Some, too, will not agree with him that active and passive movements of the injured parts at all times are an advantage C R and E L Clarke[2] have demonstrated that the patient of men might prefer a porcelain one in the meantime. The position in a child is rather different: in many children the first molars decay early and have to be extracted; and it might well be possible to transfer a child's own wisdom-tooth rudiment to the first molar socket; the time-lag in that case would not matter providing the necessary space for eruption was maintained with a dental appliance. It is not certain, however, that the transferred molar would erupt in normal occlusion with the upper teeth: the factors governing the height of an erupting tooth are not fully understood. Possibly the pressure of the occluding tooth might be the deciding factor, and in that case the implanted tooth might well erupt into normal occlusion.

And finally the use of transplants between different subjects would have to overcome obstacles which are not merely technical in a limited sense. There is evidence of innumerable antigenic differences between members of the same species, as we have lately noted.[2] Blood-transfusion is a comparatively simple operation but it would have had little practical application if there were 4000 blood groups instead of 4. Genetic and serological work here and in America suggests that this is roughly the type of problem confronting the surgeon attempting to graft adult or embryonic tissues. Lapchinski does not seem to have been greatly hampered by antigenic differences in his dogs—indeed, he does not mention these recent genetical studies. His approach is otherwise critical and his successes make his work worthy of attention. It may be that an implanted tooth germ functions as an organiser, the original cells inducing a new germ in the host though failing to survive themselves. We may look forward to a day when workers familiar with English and American genetical techniques will be able to study the work of this Russian school at first hand.

PILL'S PROGRESS

The pill-bouncing contest at the Pharmaceutical Society is one of the Entertainments At Which We Have Never Assisted. But everyone knows that the pharmacist takes an artist's pride in turning out pills like ball-bearings. The doctor's outlook is warped by memories of his own products made when a student. In those days his sense of inferiority was largely dispelled by his clinical teachers, who assured him that his lustreless and pultaceous masses would readily disintegrate in the alimentary canal and have a good chance of undergoing absorption, whereas the shining spheres of the expert could often be recovered as good as new from the fæces. The resistant pill, however, is not without virtues. It resembles the time-bomb, whose chief merit is not that it explodes but that it explodes at the right moment. The case-hardened pill can be made to pass through the stomach unchanged and liberate its contents in the lower reaches of the alimentary canal. The efficiency of the various substances used to protect the active principles in a pill mass from destruction in the gastric juice has been investigated by Lark-Horovitz and Leng[3] of Indiana, who employ radioactive indicators. The pill covering was imitated by using a gelatin capsule coated with a mixture of shellac, castor oil and alcohol. The capsule was filled with sodium chloride previously rendered radioactive by bombardment with deuterons. Liberation of the activated salt from the capsule and its entry into the circulation were signalled almost immediately by the appearance of radioactivity in the subject's extremities (the hand was used by these workers). Simultaneously the progress of the capsule along the alimentary tract was observed by means of a movable electron-counter. The one used is presumably a modification of the Geiger electron-counter, in which the electrons thrown off by a radioactive material are deflected on to a fluorescent screen where each "hit" shows as a glowing dot. Thus it was possible to say how long the capsule had been able to withstand the action of the digestive juices of the alimentary canal, and also to correlate this finding with the approximate position of the container in the stomach or intestine. It was shown that a well-made enteric coated pill released none of its contents during a stay of 2 hours in the stomach; but as soon as it passed into the intestine radioactivity appeared in the peripheral tissues and steadily increased for the next 6 hours. On the other hand, a pill which had a defective enteric coating began to liberate its contents some 20 minutes after administration and while it was still in the stomach. The effect of leakage produces a graph quite different in pattern from that which is obtained when the contents of the capsule are suddenly liberated by digestion in the bowel. Twenty-one experiments were made with hand-coated pills. It was found that 66% dissolved in the intestine and only 10% in the stomach; the corresponding figures for ten experiments made with commercial coatings were 50 and 40%. At a time when so much reliance is placed on factory-made products these results are somewhat disconcerting. This is an ingenious application of the use of "marked" atoms that has already been applied to several biochemical and pharmacological problems, such as in Whipple's work on the fate of ingested iron and J. H. Lawrence's investigations into the phosphorus metabolism of leucocytes in health and disease. It will certainly be applied to many more in the future but the investigator will need to bring to his task a fair knowledge of the newer chemistry and more than a smattering of mathematics.

METHÆMALBUMIN

The demonstration by Fairley and Bromfield that the pigment appearing in the blood-plasma in hæmolytic diseases is not methæmoglobin but methæmalbumin is now well-established. The distinction is of considerable practical importance and Fairley[1] has therefore brought together all the information that he and his co-workers have compiled so far. The spectroscope is the most useful instrument for distinguishing the various blood-pigments, but it happens that the three pigments methæmalbumin, methæmoglobin, and sulphæmoglobin all show an absorption band—the α band—in the red part of the spectrum, and although they are in different positions they are sufficiently close to make distinction by the usual direct vision spectroscope very difficult. Two lines of investigation, however, help to overcome this difficulty. Methæmoglobin and sulphæmoglobin when they appear in the blood—for example, in sulphanilamide or other drug poisoning—are confined to the corpuscles; they are not free in the plasma. Methæmalbumin, on the other hand, occurs only in the plasma and not in the corpuscles. The hæmoglobin that appears in urine is oxyhæmoglobin; if the urine is acid a proportion of this is converted in the renal tubules into methæmoglobin; methæmalbumin and sulphæmoglobin do not appear in the urine. Secondly, by treating the pigments with reducing agents, different changes are brought about. With Stokes's reagent (ammonium ferrotartrate) or dilute ammonium sulphide the α band is dispersed in the case of methæmoglobin but unaltered in methæmalbumin and sulphæmoglobin; with concentrated ammonium sulphide the α band of both methæmalbumin and methæmoglobin is dispersed while that of sulphæmoglobin remains unaltered. These changes are easily observed with the direct-vision spectroscope. Failure to distinguish between these three pigments has led to much confusion in the terminology and classification of hæmolytic diseases. "Hæmatinæmia" is a misnomer, since hæmatin when formed place Simple air conditioning can be achieved by allowing a large fan to blow through some porous material, such as hessian, which is kept wet by water siphoning from a trough But, as LEE says, the maintenance of health in hot places turns finally on the common sense and self-discipline of the resident himself He must steer a careful course between the excessive heat production induced by violent exercise and the indolence which may grow on him, mentally and physically The margin of safety in the body's reserves is reduced in tropical climates and a man can less easily afford to ignore hygiene and offer dietetic insults to his organism He must aim at a balanced diet—with a high fluid and salt intake to meet the loss in sweat—at moderation in alcohol, a high degree of cleanliness, and early attention to ailments

TOBACCO AND CANCER

IT has been long and widely held that a causative relationship exists between tobacco and cancer of the mouth and lip, but the reasons for the belief, which were well summarised by Shurch and Winterstein,[1] are slender and circumstantial Cancer of the lip is more common in men than in women, patients with leukoplakia and cancer of the mouth are more often smokers than not, cancer in pipe smokers often arises at the point where the pipe rests against the lips, when cancer occurs inside the mouth the site affected is commonly that where the smoke jet strikes it From these observations, and from recent knowledge of the synthetic carcinogenic chemicals, one might guess that tobacco smoke contains a carcinogenic chemical comparable in potency to one of the weak and slowly acting new compounds But early experimental work failed to give any support to clinical opinion Though many attempts were made to produce cancer in animals with tobacco tar or smoke yet carcinomatoids or true carcinomas were rarely observed Roffo of Buenos Aires first obtained a papillary carcinoma on the ear of a rabbit in 8 months of treatment with tobacco smoke condensed in water His next success was got in a rabbit from a jet of tobacco smoke after 3 years' treatment Others had similar isolated successes Argyll Campbell was first successful with mice, obtaining one carcinoma after 16 months of painting In *Cancer Research*, the new official organ of the American Association for Cancer Research, Flory[2] of Chicago discusses previous attempts and records his own outstanding successes Of 12 rabbits painted on the ears with tar produced by the destructive distillation of tobacco at 350–700° C all developed tumours at the site of painting between the 49th and 79th days The tumours were papillomas and carcinomatoids A destructive distillate made at 130–350° C produced 45 tumours in 16 out of 17 rabbits but did so more slowly Of these, 40 were papillomas and 5 carcinomatoids In 22 out of 24 rabbits painted with tar from tobacco smoked in pipes at 520–730° C, 38 tumours were produced in 37–374 days, 36 of these were papillomas and 2 carcinomatoids In trials on a large number of mice 15 papillomas and 2 carcinomas were produced These developed late, between 7½ and 17 months The objection may be raised that the carcinomatoids, or locally malignant tumours, of the rabbits' ear, are not carcinomas But this type of tumour is the response which the rabbit's ear makes to the application of coal tar The same tar which in mice yields 60% of carcinomas will cause mainly papillomas and carcinomatoids, with only a few metastasising growths, in rabbits Just as tar papillomas and *carcinomatoids are true indicators* of the presence of a specific cancer-producing substance in coal tar, so they point to some similar compound in tobacco smoke and tobacco tar Flory's success where so many have failed must be attributed to his methods of making the tobacco tar and smoke Many of the conditions both of production and application were of course far removed from those under which human beings smoke tobacco Nevertheless the one probably essential condition—the temperature at which the tobacco is burnt—was the same Tobacco smoked slowly in briar pipes burns at 425–560° C and rises t 600° C or even 700° C after a few puffs The temperature in clay pipes rises to 645–704° C and i cigarettes to 604–670° C The *fractions of tobacc* distillate used by Flory were made in a specially constructed still so that they could be collected at thes and other temperatures Flory's experiments, togethe with the experience of others, point to the productio *during the destructive distillation of tobacco of a wea* and slowly acting carcinogenic chemical, a conclusio which is in accord with clinical observation

TRANSPLANTED TEETH

OUR teeth never seem as personal as other parts of ou bodies We should resent premature decay in ou fingernails or the presence of moth in our hair, but whe our teeth rot in our head we are acquiescent, an experience no sense of crippling when they drop or ar pulled out The thought of transplanting a growin tooth, therefore, seems little more than a matter o gardening Two Soviet scientists, A Lapchinsky and A A Malinovsky are reported to have grown tooth rudiments in alien gums[1] They extracted teeth from anæsthetised adult dogs and transplanted into the sockets rudiments of permanent teeth taken from below the milk teeth of puppies These grew to full size in the adult dogs and the same result was achieved if the puppy had been killed on the previous day and its jaw kept in a refrigerator overnight The logical outcome of these experiments would be to discover whether the principle could be applied to human dentition—whether, for example, tooth rudiments from a child could be transferred successfully to an adult human jaw Dental surgeons already enucleate the tooth germs of the lower wisdom teeth in children when there is clinical and radiological evidence that the teeth cannot erupt normally, but there are practical difficulties to their transplantation With perfect technique successful transfer might in theory be achieved in about 60% of cases, but if the tooth follicle or the germ of the enamel organ was damaged in the process then a follicular or dentigerous cyst might *develop or the growing tooth might be malformed* A cyst might also form if the surrounding bone grew over and encapsuled the transplanted rudiment, but the growing pressure of the tooth would probably overcome this difficulty, causing absorption of the obstructing bone Sepsis might also cause trouble, healthy mouths are the rule in dogs but an adult human mouth is rarely completely free from sepsis, and the implanted tooth might well act as a foreign body causing bone necrosis Even if it were possible to obtain tooth germs from the jaws of children killed in accidents, the chance of success in transplanting would be remote, and the idea is not wholly inoffensive

A further objection to the operation is the time factor The lower incisors, for example, are formed 4½–5 months after birth and begin to erupt when the child is 6 years old, the crown is fully erupted 6 months later but the root is not formed until the child is 10 Thus an adult receiving such a transplant would only boast the crown of the tooth 6 years after the operation and would have to wait another 3½ years for the root, even the most

In England Now

A Running Commentary by Peripatetic Correspondents

THE other evening I went as usual from listening to the news straight to the surgery. Among the patients there was a man I had seen that morning and told to come up again with a tomato leaf. He was a nurseryman and had dermatitis and from its appearance at a significant time each year it seemed likely that tomatoes were the cause. The wireless was still jangling in my head as I cut the leaf for a patch test. V for victory, V for arrowhead from Heaven, V except for the proud phallic I the simplest and probably the oldest letter of them all, that points to man his origin from dust, where he shall go again, where he shall lie, the divine point driven irresistibly downwards, the piercer, the wedge of resolve, God's stream-lined spermatozoon, the emblem of union, two views culminating in one point, the conquering call of the eagle. "It's a funny thing, doctor but where I am sunburnt, on the face and this side of my arms" (he stroked the extensor surface of his arm) "and on the neck here I don't get the spots nor the itching." Nature's own cure or preventive, the light from the sun which when reflected would form a V, the light from Heaven reflected on man, V for Victory! V for a positive patch test on a nurseryman's belly, V for vengeance, V —

Gosh, this is becoming an obsession.

* * *

The alarm sounded over the ship's broadcaster, an air-attack was apparently imminent. My position in action was the officers' bathroom which made an excellent dressing station having running water (in theory at any rate) and several baths which with the addition of boards became crude but serviceable operating tables. The steriliser was switched on and the emergency lighting checked over. In the adjacent compartment the chaplain, the dental officer, my three sick-berth attendants and a motley crowd of assorted cooks and stewards had gathered, the latter constituting the first-aid parties. Stretchers and bags containing the essentials for elementary first-aid were distributed and the parties trooped away to their vantage points to await casualties. Meanwhile outside events were livening up with a vengeance as far as we down below could judge. Our position having been chosen for its comparative safety we were pretty well isolated from the happenings on the upper deck, and for our news we depended on announcements over the broadcaster or the excited and never very accurate accounts of those people who found their way below. However, the dull concussions of the bombs were pretty obvious, as were the sharper and closer explosions of our own A.A. guns and the occasional chatter of some close-range weapon.

For a time all was well though I could see my own nervous tension reflected from most of the other faces. Our experience of attacks was too small for us to have become blasé. None the less we all assumed a nonchalant air which was rather spoilt by occasional involuntary starts. At first these occurred at only the louder and more fearsome noises, but as tension grew we leapt like startled stags at even the closing of a hatch. One consolation was that the old hands, the veteran sea dogs, seemed similarly affected, though admittedly not to the same extent.

Our assumed complacency received a rude shock when, with a crescendo of loud explosions a stick of bombs fell across the ship, the last one very close to the port side, shaking us not a little both mentally and physically. We straightened up from the crouching positions we had adopted and smiled bravely at one another. There was little time for speculation though, for soon a confused shouting above with cries of "To you!" "I've got him," and "Take your foot off the blinking rope!" brought us running to the foot of a ladder leading up to a hatch through which protruded a pair of "boots regulation," neatly fastened up in a Neil Robertson stretcher. The first casualty was arriving. He proved to be a Royal Marine, who had sustained several small splinter wounds, all luckily superficial, and whose chief complaint was against the over-zealous stretcher party, who had clapped him into a stretcher to bring him down to us. Though a bit shaken he was as he maintained "in the pink." While we were dressing him the second casualty arrived—a seaman with a bad wound of his right arm showing a splintered fracture of the humerus and much loss of overlying flesh. Though in a good deal of pain and considerably shocked he was very cheerful and temporary dressings together with morphia soon had him comfortable. Inquiry on our private telephone line revealed that the other dressing station had received no casualties at all and so the total bag for the near-miss was fortunately very small. It seemed a good excuse, if excuse be ever needed in the Navy for the making of tea. So we sent the chief cook off on this errand and soon large "fannies" of it arrived, hot and incredibly strong. The casualties had first whack and then, having satisfied our consciences we proceeded to satisfy our thirsts in no uncertain manner.

This done, there was nothing to do but wait and waiting is perhaps the worst possible occupation under such circumstances. I cannot pretend that the danger was ever very great, but in our arrogant manner we assumed that we were the principal target and had ample time to analyse the various noises and think unpleasant thoughts about their proximity. Commands over the broadcaster were interspersed with greater and lesser bangs, the gunfire went on and on relentlessly, always accompanied by that curious frenzied shouting which seems to be part of the naval gunners' stock-in-trade. I imagine that the temporary deafness induced by the continuous detonations—and 4 inch is a notorious calibre for this—makes it impossible to modulate one's voice. For several hours this lasted fortunately without anything more dropping in our immediate vicinity. Then, after a long interval to make quite sure, the "secure" was sounded. The first-aid parties returned with their equipment, all was stowed away and the "disperse" sent us about our business.

While our casualties were being removed to the sick bay and prepared for operation we strolled out for a breath of fresh air on the upper deck. The fires were fading with the growing light of dawn and the smoke was drifting away from the heavily blitzed city. A dockyard policeman, veteran of many raids said with no assumed bravado, "You should have been here on Saturday night, that was a real raid that was."

Like many of his fans I was concerned to see that Mr P. G. Wodehouse had got into hot water from certain sections of the press. Being anxious to come by some reliable first-hand information on the subject I decided to ring up Jeeves—and what a pleasure it was to hear his voice again! With the possible exception of the Royal Navy I know of nothing that gives such solid confidence in the future of England as those cultured tones. "That you Jeeves?" I asked. "How are you?" "I enjoy the best of health I thank you sir." "And Mr Wooster?" "Mr Wooster I am happy to say is well. He is in the intelligence service, sir but I regret that I cannot divulge his immediate whereabouts even to you, sir. I am sure you will understand." 'Quite so, Jeeves. Now what's all this I hear about Mr Wodehouse?' "Mr Wodehouse sir? Ah that would be the literary gentleman who used to spend so much of his time with us. He is, I understand at present on the Continent, sir." Admiring his discretion and resisting the temptation to tell him to quit stalling I went on "Yes, Jeeves, but what do you think about him?" "Well, sir I always found him an exceedingly pleasant gentleman, though I cannot speak with authority about his writings not having had leisure or—ahem—inclination to peruse them. They are I believe, of a somewhat frivolous nature." "Yes, but what would you say about the man himself?" "Well, sir since you ask me and speaking in the strictest confidence I should describe him as a light-hearted gentleman, not perhaps intellectually profound but—for an author—singularly free from vice." "Thank you, Jeeves. That's just what I wanted to know. You have relieved my mind and I'm grateful to you." "Not at all, sir, will there be anything further, sir?"

* * *

I was a bit doubtful when the lady next door signed her free-milk form in block capitals whether the Minister combines at once with serum albumin to form methæmalbumin The hæmolytic methæmoglobinæmias and sulphæmoglobinæmias of van den Bergh were probably both examples of methæmalbuminæmia Methæmoglobin, so long as it remains within the corpuscles, can be converted back to oxyhæmoglobin, sulphæmoglobin, however, is an irreversible compound—lysis of red cells will release the pigments into the plasma but methæmoglobinæmia or sulphæmoglobinæmia is not produced Both these pigments have to be present in considerable amounts to be detected spectroscopically and they are probably not present as such for long, for if they are incubated with plasma at 40° C methæmalbumin is produced, and it is likely that this represents their fate in vivo Fairley suggests that hæmolytic anæmias can be put into three groups In one hæmoglobin appears in the urine, methæmalbumin and excess of bilirubin in the blood-plasma, the second is similar but without hæmoglobinuria, in the third only hyperbilirubinæmia is present In the first two groups hæmolysis is occurring predominantly in the blood stream whereas in the third the reticulo-endothelial system is responsible We have standard methods for detecting hæmoglobin in the urine and bilirubin in plasma or serum, methæmalbumin can be demonstrated by direct spectroscopy only if considerable amounts are present, but it can be converted by a reducing agent into a spectroscopically sensitive hæmochromogen with a clearly defined absorption band at 558 $m\mu$ (yellow-green) This reaction is known as Schumm's test and was originally used to detect the presence of hæmatin, but from what has already been said it is clear that a positive reaction in a specimen of serum indicates the presence of methæmalbumin, and this is the best way of detecting methæmalbumin The test is carried out by covering a known volume of serum with a layer of ether and then running in with a pipette one-tenth the volume of concentrated ammonium sulphide and a few drops of ammonia, the mixture is shaken and the direct vision spectroscope can then be used to look for the characteristic absorption band. The van den Bergh test for bilirubin is asked for in every case of suspected hæmolytic anæmia, Schumm's test should be used just as often

FIRST-AID FOR BURNS

THE differences of opinion and changes in practice with regard to tannic acid have led to some confusion in both laymen and doctors called on to apply first aid to burns In E M S Memo No 7 (H M Stationery Office, pp 4, 2*d*), issued by the Department of Health for Scotland, the principles as modified by modern views are restated In local treatment the layman is told to cover the exposed parts of the burn with a clean dry sheet, towel or cloth, and under no circumstances to apply oil, grease, flour, soot, baking soda or lysol The medical attendant is advised in severe cases, which include all burns of the face and eyes, hands and feet, to control pain with morphine rather than local applications, this implies that before moving the patient to hospital he should keep to dry dressings The moderate burn which can be treated fully at the first aid post should be cleansed before the application of a coagulant, using soap where necessary, followed by saline, and avoiding ether or alcoholic solutions and vigorous rubbing or scrubbing For general use a coagulant in a water-soluble base is advised The recommendations for difficult areas are usefully illustrated in a diagram and summarised as follows

Palmar surfaces of fingers and hands —Snip blisters, but do not remove epidermis Apply gauze soaked in 1/1000 euflavine

Flexures —After cleansing and removal of epidermis, apply gauze soaked in 1/1000 euflavine

Face —After cleansing, apply jelly spread on a mask of gauze cut to fit with holes for eyes, nostrils and mouth

Eyelids —Eyelids should never be coagulated, but thick smeared with sterile soft paraffin

Mucous surfaces of lips and mouth —Apply sterile sc paraffin

Ears —Before cleansing, plug lightly with cotton wo smeared with sterile soft paraffin After cleansing, sme thickly with sterile soft paraffin

Hairy parts —These must be shaved for at least 2 in round the margin of the burn before cleansing with ster saline

It will be seen that the memo follows the lines of th issued by the Ministry of Health in February (see *Lanc* March 29, p 425), but here no attempt is made to disc treatment in hospital

GUY'S IN THE WILDERNESSE

AT the suggestion of the Ministry of Health Gu has, for obvious and cogent reasons, opened a coun branch at the Wildernesse Club at Seal, near Sevenoa The first patients moved in on June 30, and on Jul the annexe was formally opened as "Guy's U S Hospital" The transatlantic flavour of the name a token of the hospital's gratitude to the Bundles Britain Association which has given 10,000 dollars pay for the adaptation of the house into a hospit At the opening, Mrs Edward Murrow, their represen tive in this country, said that the general pro-Brit feeling which exists in America needs to be harness to particular objectives with a tangible human app more satisfying than an intellectual passion democracy The Hollywood branch of the organis tion has accordingly adopted Guy's, and the advanta of hitching your wagon to a galaxy of stars is clear, Hollywood has already promised a much needed de X ray therapy plant, fracture beds, and a gastroscop while Mr Harry Warner has given £900 to furnish operating theatre The new annexe has 120 beds an the resident staff will include a medical superintende and two medical officers, a lady superintendent, eigh sisters, and fifty nurses, while physicians and surgeon from Guy's will be regular visitors The patients wil be air-raid casualties and other civilian sick transferre from the mother hospital The reactions of patient and staff to a country life will be recorded for con sideration when the time for post war reconstructio comes

THE KING AND THE COLLEGE OF SURGEONS

AT a meeting last week of the council a letter was rea from Sir Alexander Hardinge, private secretary to th King, who is Visitor to the Royal College I am t assure you, the letter runs, that it is a source of dee regret to His Majesty to learn of the damage to th museum buildings and the loss of valuable specimen resulting from enemy action The King is, howeve much gratified to hear of the further generous gift mad by the Bernhard Baron trustees towards the endowmen of the professorship of research, which will go far t prevent any of the regrettable interruption which migh otherwise have occurred in the scientific work an development of the college

SIR ALFRED WEBB JOHNSON has been elected presiden of the Royal College of Surgeons in succession to Si Hugh Lett

AWARDS IN THE R A M C —The following awards hav been made to medical officers in recognition of distinguishe services in the Middle East

C B —Colonel (temp Major General) P S Tomlinson D S O, M R C P, A M S

I was a bit doubtful when the lady next door signed her free-milk form in block capitals whether the Minister of Food would accept that as a signature I took the advice of the Law

Dear MIKE (wrote the Law),—All right, I'll ask you another What d'you mean by signature ? If it is just your name on a form for some official purpose, the Government 'll tell you the way it wants you to sign If it is the signing of a name to show that the writing accords with your wishes or intentions, then the law will tell you what minimum it insists upon In this connexion it will often accept your initials or just your mark, if they're intended to represent your name And signature by a duly accredited agent will also do For signing a will, it's enough to affix a mark, or stamp with an engraved signature, or put your initials But it ain't enough to trace a former signature with a dry pen, because it leaves no physical sign The signature to a will ought to be your real name, but where a lady called " Glover " signed as " Reeve " (her first husband's name), the will was held validly executed In legal proceedings I believe it has been held that particulars filed in a county court action, where the solicitor's name at the end was merely lithographed, were not " signed " , if the solicitor's clerk had signed for him, it would have been O K For certain purposes, in contracts and documents creating obligations, the Statute of Frauds requires the document to be signed by the party who is to be charged Initials have been held to suffice for this I don't know that this answers your question which perhaps arose out of a distinction between signature and usual signature The bank knows our " usual signature " to our cheques We could alter it, if we liked , but if we kept altering it, the result would be a lot of inconvenience to ourselves as well as to the bank We want to be able to answer confidently if anybody asks " Is this your signature ? " And so no more at present from—UNCLE BOB

* * *

A round at hospital has revealed that Anna is back again She is a toxæmia of pregnancy with albuminuria The local hospital and I play battledore and shuttlecock with her, they not caring for the sight of her any more than I do When the B P soars to terrifying heights I send her in for surgical induction, when it subsides they send her out The score at the moment is vantage nobody (the patient not excepted), my service Sister, a professional gleam in her eye, asks if I have seen Mrs S——'s foot ? The question is purely rhetorical, as Mrs S has been admitted for myocardial degeneration Her foot certainly presents a unique, and to me undiagnosed problem The entire surface of the heel is covered with soft warts which pressure has flattened out into thin, pulpy, plates with a central pedicle These plates are fitted into one another like a piece of mosaic, and the condition is complicated by advanced varicose veins The cure and treatment, if any, has not yet occurred to me

Harness, the six-year old diabetic, is leaning out of the baby-room window " Someone mit move these babies," he begins indignantly on sighting me " They make too much noise " The noise certainly is appalling, but as Sister and I point out he is under no obligation to stay in the room Harness pouts, and we realise that his objection to the nursery is the presence of Maria, an old-fashioned party of five and a half who sets Sister and me right on matters of hygiene " No thank you," she says with frigid politeness when we offer her a piece of barley-sugar " It's been in the same room as the sick babies " Despite the screw-top to the jar, we feel snubbed, and help ourselves to pieces with overacted enthusiasm Secretly we sympathise with Harness and to change the subject Sister reminds him that there was something he wanted to tell doctor Harness goes very pink, stutters, and finally gets the story out with a rush Toilet paper had run out, and one of the nurses had presented him with a piece of newspaper till she had time to fit a new roll , on it was a photograph of Hitler " I used it," he announced with awful emphasis, " and then I pulled the plush on him " He giggles, stares intently at us both, and deciding that we lack entertainment value turns back to the window " Are the gulls interned ? " he asks, watching them as they beat up wind to the headland

SHAFTESBURY MILITARY HOSPITAL MEDICAL SOCIETY —A meeting of this society will take place on Tuesday, July 22, at 3 P M , when Major F R Bettley, R A M C , will speak on the early diagnosis of common skin diseases

THE BIOLOGY OF EPIDEMICS

Abstract of the Croonian Lecture given by Prof W TOPLEY *before the Royal Society on July* 17

THE universe of study which today faces the ep logist is not, in its essence, composed of a number of a clinically recognisable disease, with a dist that varies in an observable way in space and ti is composed of a variety of biological species, som as parasites and some as hosts The parasites viruses, or bacteria, or protozoa, or worms Th may be men, or animals, or insects, or plant parasite may pass from host to host by direct by indirect mechanical contact, or through the of an insect vector In whatever way it passes, t factor that determines the occurrence and typ epidemic prevalence is the frequency of its passa

If all relevant environmental conditions are he stant, and susceptible hosts are added at a hi steady rate to an infected herd, a steady rate of m is attained, with no major waves or fluctuatio with a steady rate of addition, the closeness of between host and host is changed, increased clos contact is followed by the propagation of a ma demic wave, and decreased opportunity for conta rapid fall in the mortality-rate These exper observations have many analogies in the record valence of infectious disease under natural condit

During an epidemic prevalence the average re of the hosts rises with length of exposure to r part because of the elimination by death of th susceptible individuals, in part because of the immunisation of survivors The resistance atta this way, though sometimes high, is never absolut can, in many cases, attain the advantages of immunisation, without its risks, by an appr method of vaccination

Differences in severity between different epide the same disease are in part accounted for by bi differences between various strains of a single p species, between different races of a single species or between different races of a single species o vector The biological characters that determi ability of a parasite to spread from host to host identical with the characters that determine its to multiply rapidly in the host's viruses, so that vi and infectivity may vary independently

In attempting to control epidemics we always st one way or another, to decrease the probability passage of the causative parasite from an infect susceptible host We may do this by changes distribution of the hosts at risk, or by lessen population density of an essential insect vector, reducing the proportion of susceptible hosts by a immunisation, or in many other ways In no ca necessary, by our own action, to reduce the probal zero The epidemic system is in unstable equil If we tip the balance far enough in favour of the system itself will do the rest, and the disease will become very infrequent, and may sometimes dis

SCOTLAND

ADMISSION TO E M S HOSPITALS

THE Department of Health for Scotland has anno that whole-time civil defence workers transferred their homes, and trainees in Ministry of Labour ind establishments who have been moved from their are eligible for admission to E M S hospitals patients, in accordance with normal hospital pr will be given an opportunity of contributing to the cost of their treatment Whole-time civil d workers are already eligible for admission, whethe are in their home areas or not, for treatment o service injuries and fractures sustained whether o service or not The new extension includes sickn injury sustained while not on civil defence servi while living away from home

SUMMER GRADUATION IN ABERDEEN

Dr W Hamilton Fyfe, the principal of Aberdeen University, in addressing the new graduates last week said that civilisation did not consist in a material standard of living, moral standards were even more important It was for moral standards we were fighting—mutual trust fair dealing, sympathy, mercy and goodwill, and for a genuine respect for the interests of the human intellect and spirit The price of freedom was eternal vigilance, and the price of civilisation was a sense of responsibility One nation after another had been enslaved because each considered its own interests in isolation Slavery awaited all men and women who did the same Their sense of responsibility required that they should answer any call for service however uncongenial and hard It made also one of those more trivial demands, often harder to meet than the calls for great sacrifice When rules were framed to secure for all an equal share of food, clothing or petrol, they must set an example which will put to shame those stupid and treacherous people who try to evade the rules and get more than a fair share for themselves And on them also lay the responsibility for rebuilding and securing and improving the civilisation of Europe when the war is over That might prove the hardest and heaviest responsibility of all, but they were privileged people to whom much was given, and of whom much was required

HONYMAN GILLESPIE LECTURES

The following lectures will be given during the summer vacation at 4 30 P M on Thursdays, at Edinburgh Royal Infirmary July 24, Prof D M Lyon, significance of a systolic murmur, July 31, Prof L S P Davidson, biopsy of the sternal bone-marrow as a diagnostic procedure, Aug 14, Prof D K Henderson, the significance of fear, Aug 21, Dr A Rae Gilchrist, the hypertensions, Aug 28, Sir John Fraser, the antiseptic eras—yesterday and today, and Sept 4, Prof D M Dunlop, the dietetic treatment of gastro-intestinal disease The lectures are open to graduates and senior students

Parliament

Pharmacy and Medicines Bill

Mr Ernest Brown broke a twenty-five-year-old parliamentary hoodoo in sponsoring this bill which came before the House of Commons for second reading on July 8 and which, he rightly said, involved a very old and controversial story The new bill, in accordance with the Chancellor of the Exchequer's promise, repeals the Medicines Stamp Acts which have become unworkable—indeed the High Court has stigmatised them as "a mass of confused and obsolete verbiage" The general proposition of the select committee of 1937 that medicines could suitably be taxed at $16\frac{2}{3}\%$ ad valorem, which formerly met with much opposition, had now been carried into effect by the Purchase Tax, and the estimated yield of the tax on medicine is 3 million pounds a year, or nearly four times the yield of the Medicine Duty

There were strong reasons against sweeping away the advantages which chemists enjoyed under the present law, and the bill embodied an agreement accepted by most of the trade interests concerned which substituted a trading privilege for a financial advantage Clause 7 provides that from the date of repeal of the duties all medicines shall be sold retail only by chemists, together with doctors and dentists, with the exception of herbal remedies, of mineral waters, and of proprietary medicines not described in the B P or B P C There was, Mr Brown added, no desire on anyone's part to interfere with the legitimate practice of legitimate herbalists

Today there were still opportunities for the unscrupulous to trade on the credulity and fears of the ill-informed, and the advertisement of quack remedies often delayed the seeking of proper advice This bill would stop these practices From Jan 1, 1942, all medicines must bear a statement of their composition or active constituents, the only exception is a medicine supplied to an individual prescribed according to his needs—for instance a mixture made up in accordance with a doctor's prescription The advertisement of remedies for certain diseases, or of articles for procuring abortion, would be stopped Advertisements of articles for the treatment of venereal disease and cancer are already prohibited by law and the present bill extends the prohibition to advertisements of remedies for Bright's disease, cataract, diabetes, epilepsy or fits, glaucoma, locomotor ataxy, paralysis and tuberculosis The bill also makes minor amendments to the Pharmacy and Poisons Act, 1933 A retailer who sells drugs including poisons at a chemist's shop need not have a pharmacist in charge of other shops where he sells drugs other than poisons The statutory committee of the Pharmaceutical Society when adding or restoring a name to their register may take into account any offence committed by the applicant while not registered They are also authorised to remove or withhold names from the register for a stated period Mr Brown said the bill was the result of infinite shrewdness and goodwill, and he commended it to the House as the first legislative step for a generation on the road to reform

In the debate which followed members showed a generous indignation that the gullible should be expensively duped Many thought the measure did not go far enough, while others were anxious that herbalists should have a fair deal Mr James Griffiths urged that the real remedy lay in the advance of education and the provision of adequate medical services Mr Beverley Baxter thought the B M A was reactionary but had found herbalists to have social charm Prof A V Hill rushed to the rescue of the medical profession, and deplored people who scrupulously obey the law the Ten Commandments and Mrs Grundy and only show their liberalism by favouring quack medicines He reviewed with wit and distaste the advertisements of some popular remedies and welcomed the bill which was overdue We had been respectful and tolerant far too long of the exploitation of the sick and suffering

Mr Henry Strauss agreed with Lord Horder that the advertisements of patent remedies often constituted a greater danger to health than the contents of the medicines themselves Unless the Government were prepared to go much further in the control of advertisements it would be better to drop Clause 3 and combat the evil by sowing distrust in the public mind Sir Ernest Graham-Little supported the bill though he was disappointed in its character and its scope A sum of 30 million pounds a year was extracted from the public for patent medicines, more than was spent on all the hospital services Advertisements of patent medicines in the newspapers produced a disease consciousness He agreed with Mr Strauss that the restrictions on advertisements did not go far enough and he doubted whether they would have much effect The bill states that the description of a remedy may take the form of a reference to it in the B P But, Sir Ernest asked, did the purchaser of medicine in a shop know the British Pharmacopœia? Mr Rhys Davies pointed out that 20 million out of our population of 44 million were entitled to free medicine under the National Health Insurance scheme If the sale of proprietary medicines was still being maintained that was a commentary on the gullibility of the public He also raised the question of surgical appliances If it had not been for the Ministry of Health and the approved societies there would have been a first-class racket in some of these appliances

Captain G Elliston did not pretend to have wholehearted enthusiasm for this measure The weakest point was the absence of any enforcement clause Suggestions would be made in committee for the creation of an advisory controlling body for the registration and supervision of proprietary medicines Sir Dymoke White said that a large body of retail pharmacists, including the National Pharmacists Union, was alarmed at many of the proposals Sir Francis Fremantle admitted that the bill did not go far enough because it did not compel disclosure of the quantities of the component parts, but he thought it was a step in the right direction He spoke up for the B M A which had done its best to run down the gross frauds and quackery in the patent medicine trade

Miss F Horsbrugh, who replied for the ministry, promised consideration for the points raised She agreed that this country needed a constructive health policy, but in order to build we had to demolish The bill was read a second time

The Seaman's Diet

In the House of Lords on July 8 the Earl of CORK and ORRERY made a further plea for equal rights for merchant seamen when in hospital He explained that he was not alluding to medical treatment but to diet For instance, the Royal naval rating received 2⅝ lb of meat in a week, whereas the merchant seaman only got a shilling's worth, or less than 1 lb , the naval rating got 10½ oz of butter, the merchant seaman 6 oz , the naval rating got 1 lb 8 oz of sugar and the merchant seaman 8 oz , the naval rating got 9 oz of bacon and the merchant seaman 4 oz When he raised this matter about six weeks ago[1] Lord Croft had stated that the Government were satisfied that both classes of patient were getting the food current supplies allowed and their medical condition required But in view of these figures one could only think that one class of man was getting too much or the other too little Lord Cork and Orrery quoted from a letter written by a physician who gave up his spare time to caring for sailors of the merchant marine The doctor wrote that during the past year it had become increasingly clear that extra food allowances were highly desirable in the Seamen's Hospital since many of the patients were admitted in a debilitated state after long voyages or prolonged exposure in open boats No small number of the conditions which the hospital was called upon to treat were the outcome of faulty and deficient diet on board ship The doctor added that there was no doubt that the increased dietary offered by Service hospital rations would enable physicians and surgeons to get their sailor patients back into service more quickly

Lord WOOLTON said that six weeks ago an alteration was made in merchant seamen's rations and now except for meat the two Services were treated alike In hospital the rations went into a common pool and each man got what was necessary for him according to the opinion of his medical attendant If there was any shortage of food for merchant seamen, or for any other class of seamen, who were being treated in hospitals, he promised to see it put right But he had received no complaints But in deference to Lord Cork and Orrery he had referred the amount of food used in hospitals treating merchant seamen once more to the Medical Research Council for advice as to whether the dietary was sufficient, and if in the opinion of the council the dietary was not sufficient he would at once increase it But if he was advised that it was not necessary he hoped that Lord Cork and Orrery would be satisfied The Earl of Cork and Orrery thanked Lord Woolton for his sympathetic reply, but said that he could not agree with him, for as vice-chairman of the Seamen's Hospital Society he had received the dietary figures which he had quoted that morning from the secretary The society had five hospitals and two convalescent homes and the information of the alteration given by Lord Woolton had not reached those hospitals

Extended Benefits

On July 10 in the House of Commons Mr ERNEST BROWN, Minister of Health, introduced the National Health Insurance Contributory Pensions and Workmen's Compensation Bill, a measure to increase the rates of sickness and disablement benefit and the rates of contribution payable under the acts relating to National Health Insurance, to extend the said acts to persons employed otherwise than by way of manual labour at a rate of remuneration exceeding £250 a year, and in connexion therewith to amend the acts relating to widows', orphans' and old age contributory pensions and certain other enactments , to enable any of the acts aforesaid to be adapted by regulations to war-time conditions , and to amend paragraph (*a*) of subsection (2) of section three of the Workmen's Compensation Act, 1925 The bill was read a first time

QUESTION TIME

Orthopædic Treatment in Scotland

Mr T JOHNSTON replying to Dr H B MORGAN said I am aware that facilities for fracture treatment in Edinburgh and Glasgow are not generally in full accordance with the recommendations of the Delevingne committee but some progress has been made since the publication of the report Moreover in developing the Emergency Hospital Services special attention has been given to arrangements for the treatment of fractures including the provision in Scotland o 6 entirely new orthopædic units (with associated provision fo occupational therapy providing 2000 beds) These facilitie are available not only for the treatment of civilian wa casualties but also for certain manual workers whose earl return to work is of special importance As regards cond tions which occasion crippling other than fractures I hav encouraged schemes initiated by voluntary bodies for th improvement and extension of facilities for their treatmen

Venereal Disease in Jamaica

In reply to questions from Dr MORGAN Mr GEORGE HAL Under Secretary of State for the Colonies, stated There a different departments in the venereal diseases clinic at Kingst for males and females, but owing to lack of space and st there are not separate departments for children There a no special facilities in the hospitals for treating childr suffering from these diseases and the great majority infected children are treated at the clinic as outpatient It is not the general rule for a child attending the clinic to accompanied by an adult member of the family except first visit The Minister does not regard this position satisfactory and he is taking up the whole matter with th Governor of Jamaica

There are three clinics for the treatment of venereal disease in Jamaica, situated at Kingston, Montego Bay and Po Antonio Four full time and two part time medical office are attached to the Kingston clinic and one part time medic officer to each of the other two clinics The governor state that it is impossible to estimate the proportion of thos infected who seek treatment at the clinics It is know however, that an exceedingly small proportion of cases eve seek competent medical treatment in the early stage Th greater percentage only do so if late unpleasant complication develop The following numbers of new cases were admitte to the clinics in 1940

Kingston	Gonorrhœa	M	2691	F	405
	Syphilis	M	1624	F	219
Montego Bay	Gonorrhœa	M	1056	F	110
	Syphilis	M	504	F	44
Port Antonio	Gonorrhœa	M	800	F	506
	Syphilis	M	758	F	489

M = Male, F = Female

A temporary clinic at Kingston public hospital is equipped but is not in operation owing to the lack of staff Clinics are also planned for Spanish Town, St Anne's Bay, Falmouth, Savanna La Mar, Black River and Mandeville, when funds are available

National Health Insurance Benefits

Mr J J TINKER asked the Minister of Health if he was aware of the different rates of benefit paid by societies under the National Health Insurance scheme , and would he give consideration in the Bill he was to introduce to the pooling of all funds, so that one rate of benefit could be given to all insured persons —Mr BROWN replied The answer to the first part of the question is Yes The bill is designed to give effect to certain changes in the health insurance scheme necessary to meet war time conditions, and the proposal referred to will doubtless be one of the issues to be considered by the committee which has been appointed by the Minister without Portfolio to undertake a comprehensive survey of the existing schemes of social insurance

Alien Doctors

Mr GEORGE STRAUSS asked the Minister whether he would extend the scheme whereby the services of doctors of allied and friendly nationality were employed in certain hospitals and institutions to cover those few doctors resident in Great Britain who had obtained their degrees in Switzerland, Sweden and other neutral countries —Mr BROWN replied The question of making a further order under Defence Regulation 32B so as to include the classes of doctors referred to is receiving consideration

Price and Delivery of Milk

Sir HENRY MORRIS JONES asked the Parliamentary Secretary to the Ministry of Food why the producer of milk from best attested herds only received 1*s* 4½*d* per gallon, including cost of transport to wholesalers, whereas the retailer received 2*s* 8*d* per gallon —Major G LLOYD GEORGE replied The return to the milk producer varies slightly according to the Milk Marketing Board region in which he is situated The retail price of milk also varies according to population areas The figures quoted are substantially correct for North Wales for June, 1941 The retailer does not himself retain the difference between the price to the producer and the price to the consumer He purchases his milk at the regional price which in June was 1s 8½*d* per gallon. Furthermore, the retailers' margin varies from month to month, being in England and Wales generally higher in the summer months than the winter months, while the return to the producer is higher in the winter than the summer It is therefore misleading to base any comparison of producers and retailers' earnings on the figures of any particular month

---

[1] See *Lancet*, May 31, 1941, p 710

In answer to a further question Major LLOYD GEORGE stated While the practice of restricting milk deliveries to six days a week is substantially less prevalent than a month ago, there are still towns and villages where a milkless day operates The Minister has appealed to distributors to maintain a 7 day delivery service in the interest of the consumer The great majority of distributors has responded to this appeal Consideration is being given to the further action which might be taken in those centres where the appeal has so far proved fruitless

Occupational Therapy in Mental Hospitals

Mr F MESSER asked the Minister of Health if he was aware that the present rationing of materials is hindering the work of occupational therapy in mental hospitals, and if he could take steps to secure a relaxation of the rationing regulations in these special cases —Mr BROWN replied I am in communication with the President of the Board of Trade in this matter

---

Letters to the Editor

SAVING ON DRUGS

SIR,—Arising out of Dr Pappworth's letter on this important subject in your issue of July 5, it may be of interest to set out what has been done in the hospitals of the London County Council The purchase of drugs by contract and otherwise is in the hands of experts on the staff of the chief officer of supplies they advised me in April, 1940, that there was actual and potential shortage of many drugs and I forthwith established a committee of hospital medical officers and pharmacists to revise our pharmacopœia and drug schedules On June 4, 1940, a circular, from which the following are extracts, was issued to all hospitals with, as is our routine practice, a copy to each pharmacist —

> " Considerable difficulty is being experienced at the present moment in obtaining supplies of drugs, medicines, etc, required for the treatment of patients in the Council's ospitals owing to the war and to difficulties in overseas ansport
>
> The questions whether various kinds of drugs could be educed in number or adequate substitutes found have been ery carefully considered and a statement is attached which ontains suggestions whereby such economies can be secured he question of transport not only affects drugs from overseas ut affects also the distribution of drugs from the firms pplying them, owing to the restriction of petrol supplies, nd it is imperative as far as possible to restrict the number f deliveries
>
> "In the schedule which is attached it is recommended at certain articles should be issued only for use in particular nds of wards, e g, tuberculosis wards, and it is hoped that ou will ensure that this request is carried out to its fullest xtent
>
> With regard to the use of proprietary medicines, every ffort should be made to restrict their use and British subtitutes of official preparations and reputed analogous herapeutic effect should be used where possible I attach or your information and for that of the pharmacist, a handook entitled Pharmaceutical Specialities, issued by the ssociation of British Chemical Manufacturers
>
> "Your special attention is also drawn to the fact that both live oil and glycerine are controlled and that the amounts vailable are severely restricted Both must be used as paringly as possible
>
> "It is also suggested on the grounds of economy that all he developing and fixing solutions for use in the X ray epartment or cardiographic department, if any, should be ade at the hospital "

The schedule attached to this letter comprised 86 drugs or preparations Since that date several other circulars have been issued drawing attention to shortage or unavailability of other drugs and copies of all recommendations as to the use of drugs, &c, emanating from the Ministry of Health or the M R C have been sent to all medical superintendents and pharmacists Careful scrutiny of drug requisitions is maintained at head office and, as it is only rarely that deletion or substitution is called for, I am satisfied that in the L C C hospital service the desire to economise, which Dr Pappworth rightly insists on, undoubtedly exists and is loyally acted upon

County Hall S E 1 W ALLEN DALEY
Medical Officer of Health

SHORT ŒSOPHAGUS AND PEPTIC ULCER OF THE ŒSOPHAGUS

SIR,—In your issue of July 5 you refer to a communication Dr P J Briggs, Dr R C S Dick and I made before the medical section of the R S M in 1939 (*Proc R Soc Med* 1939, 32, 1423), in which we stated that peptic ulcer of the œsophagus is almost always associated with that form of hernia of the upper part of the stomach through the diaphragm which is caused by congenital shortening of the œsophagus According to your annotation Dr A S Johnstone has recently described 7 cases of chronic œsophageal ulcer, in all of which there was definite shortening of the œsophagus He regards the short œsophagus as secondary to cicatricial contraction of the ulcer, and not, as we maintained, the predisposing cause The main reason for this appears to be that in his experience œsophageal ulcers occur at an advanced age, the average in his series being 64, as symptoms might be expected to develop much earlier if the condition were associated with a congenital abnormality But the age at the onset of symptoms in our 7 cases of chronic peptic ulcer in a short œsophagus varied between 18 and 58 the average being 41 In the only case we have found in the literature the shortening was obviously congenital, as the patient was only three years old and vomiting of blood-stained material had begun at the age of one week (Haroen, I L and Gerlings, P G *Acta oto-laryng Stockh* 1934, 19, 461)

We believe that a short œsophagus predisposes to the development of a peptic ulcer because for some unknown reason the cardiac sphincter is incompetent when the œsophagus is congenitally short, whether an ulcer is present or not Opaque fluid can be seen with the X rays to regurgitate into the œsophagus from the stomach on lying down, whereas no such regurgitation occurs under normal conditions Consequently acid gastric juice is likely to enter the lower end of a congenitally short œsophagus at night and produce erosions which may develop into chronic ulcers Owing to this regurgitation most patients with chronic œsophageal ulcers experience pain behind the lower end of the sternum immediately they lie down at night as well as while eating, and healing is hastened and recurrence prevented by having the head of the bed permanently raised on blocks

Oxford ARTHUR HURST.

THE FRONTAL LOBES

SIR,—I wondered how long it would be before the erstwhile insulin, Cardiazol and electrocution enthusiasts, having become tired of inflicting minor injuries on the cerebrum, got wind of the new whole-hogging technique and dashed in, with careless rapture, to the mutilation of the frontal lobes I take it that their former adventures will now be allowed to sink into respectable oblivion

Lest in what follows I should be accused of having allowed my emotions to run away with my reason I should like to point out that the new procedure consists in inflicting severe injury on a part of the brain the function of which has not yet been precisely determined in order to cure disorders of the cause of which we are largely ignorant Not that I am so much against empirical procedures of this kind provided that the work is done well and scientifically which means the selection of a special type of mental disorder for investigation the accumulation of an adequate number of such cases before publication, accurate and detailed psychological assessment before and after treatment, and careful

The Seaman's Diet

In the House of Lords on July 8 the Earl of CORK and ORRERY made a further plea for equal rights for merchant seamen when in hospital He explained that he was not alluding to medical treatment but to diet For instance, the Royal naval rating received 2⅜ lb of meat in a week, whereas the merchant seaman only got a shilling's worth, or less than 1 lb , the naval rating got 10½ oz of butter, the merchant seaman 6 oz , the naval rating got 1 lb 8 oz of sugar and the merchant seaman 8 oz , the naval rating got 9 oz of bacon and the merchant seaman 4 oz When he raised this matter about six weeks ago[1] Lord Croft had stated that the Government were satisfied that both classes of patient were getting the food current supplies allowed and their medical condition required But in view of these figures one could only think that one class of man was getting too much or the other too little Lord Cork and Orrery quoted from a letter written by a physician who gave up his spare time to caring for sailors of the merchant marine The doctor wrote that during the past year it had become increasingly clear that extra food allowances were highly desirable in the Seamen's Hospital since many of the patients were admitted in a debilitated state after long voyages or prolonged exposure in open boats No small number of the conditions which the hospital was called upon to treat were the outcome of faulty and deficient diet on board ship The doctor added that there was no doubt that the increased dietary offered by Service hospital rations would enable physicians and surgeons to get their sailor patients back into service more quickly

Lord WOOLTON said that six weeks ago an alteration was made in merchant seamen's rations and now except for meat the two Services were treated alike In hospital the rations went into a common pool and each man got what was necessary for him according to the opinion of his medical attendant If there was any shortage of food for merchant seamen, or for any other class of seamen, who were being treated in hospitals, he promised to see it put right But he had received no complaints But in deference to Lord Cork and Orrery he had referred the amount of food used in hospitals treating merchant seamen once more to the Medical Research Council for advice as to whether the dietary was sufficient, and if in the opinion of the council the dietary was not sufficient he would at once increase it But if he was advised that it was not necessary he hoped that Lord Cork and Orrery would be satisfied The Earl of Cork and Orrery thanked Lord Woolton for his sympathetic reply, but said that he could not agree with him, for as vice-chairman of the Seamen's Hospital Society he had received the dietary figures which he had quoted that morning from the secretary The society had five hospitals and two convalescent homes and the information of the alteration given by Lord Woolton had not reached those hospitals

Extended Benefits

On July 10 in the House of Commons Mr ERNEST BROWN, Minister of Health, introduced the National Health Insurance, Contributory Pensions and Workmen's Compensation Bill, a measure to increase the rates of sickness and disablement benefit and the rates of contribution payable under the acts relating to National Health Insurance, to extend the said acts to persons employed otherwise than by way of manual labour at a rate of remuneration exceeding £250 a year, and in connexion therewith to amend the acts relating to widows', orphans' and old age contributory pensions and certain other enactments , to enable any of the acts aforesaid to be adapted by regulations to war-time conditions , and to amend paragraph (*a*) of subsection (2) of section three of the Workmen's Compensation Act, 1925 The bill was read a first time

QUESTION TIME

Orthopædic Treatment in Scotland

Mr T JOHNSTON replying to Dr H B MORGAN said I am aware that facilities for fracture treatment in Edinburgh and Glasgow are not generally in full accordance with the recommendations of the Delevingne committee but some progress has been made since the publication of the report Moreover in developing the Emergency Hospital Servic special attention has been given to arrangements for th treatment of fractures including the provision in Scotland 6 entirely new orthopædic units (with associated provision f occupational therapy providing 2000 beds) These faciliti are available not only for the treatment of civilian w casualties but also for certain manual workers whose ea return to work is of special importance As regards con tions which occasion crippling other than fractures I ha encouraged schemes initiated by voluntary bodies for t *improvement and extension of facilities for their treatme*

Venereal Disease in Jamaica

In reply to questions from Dr MORGAN Mr GEORGE HA Under Secretary of State for the Colonies, stated There different departments in the venereal diseases clinic at Kingst for males and females, but owing to lack of space and st there are not separate departments for children There no special facilities in the hospitals for treating childr suffering from these diseases and the great majority infected children are treated at the clinic as outpatien It is not the general rule for a child attending the clinic to accompanied by an adult member of the family except first visit The Minister does not regard this position satisfactory and he is taking up the whole matter with t Governor of Jamaica

There are three clinics for the treatment of venereal diseas in Jamaica, situated at Kingston, Montego Bay and P Antonio Four full time and two part time medical offic are attached to the Kingston clinic and one part time medi officer to each of the other two clinics The governor sta that it is impossible to estimate the proportion of th infected who seek treatment at the clinics It is know however, that an exceedingly small proportion of cases ev seek competent medical treatment in the early stage T greater percentage only do so if late unpleasant complicatio develop The following numbers of new cases were admitt to the clinics in 1940

Kingston	Gonorrhœa	M	2691	F	40
	Syphilis	M	1624	F	21
Montego Bay	Gonorrhœa	M	1056	F	110
	Syphilis	M	504	F	44
Port Antonio	Gonorrhœa	M	800	F	50
	Syphilis	M	758	F	4

M = Male , F = Female

A temporary clinic at Kingston public hospital is equippe but is not in operation owing to the lack of staff Clinics ar also planned for Spanish Town, St Anne's Bay, Falmout Savanna La Mar, Black River and Mandeville, when fund are available

National Health Insurance Benefits

Mr J J TINKER asked the Minister of Health if he wa aware of the different rates of benefit paid by societies und the National Health Insurance scheme , and would he giv consideration in the Bill he was to introduce to the poolin of all funds, so that one rate of benefit could be given to a insured persons —Mr BROWN replied The answer to th first part of the question is Yes The bill is designed to giv effect to certain changes in the health insurance schem necessary to meet war time conditions, and the propos referred to will doubtless be one of the issues to be consider by the committee which has been appointed by the Minist without Portfolio to undertake a comprehensive survey of th existing schemes of social insurance

Alien Doctors

Mr GEORGE STRAUSS asked the Minister whether he woul extend the scheme whereby the services of doctors of allie and friendly nationality were employed in certain hospital and institutions to cover those few doctors resident in Grea Britain who had obtained their degrees in Switzerland, Swede and other neutral countries —Mr BROWN replied Th question of making a further order under Defence Regulatio 32B so as to include the classes of doctors referred to receiving consideration

Price and Delivery of Milk

Sir HENRY MORRIS JONES asked the Parliamentar Secretary to the Ministry of Food why the producer of mil from best attested herds only received 1*s* 4½*d* per gallon including cost of transport to wholesalers, whereas the retaile received 2*s* 8*d* per gallon —Major G LLOYD GEORG replied The return to the milk producer varies slightl according to the Milk Marketing Board region in which he ave been special problems in other directions to solve t the outbreak of hostilities only one of the better-nown settlements was requisitioned, in part at least y the Emergency Medical Service Its geographical osition near Maidstone made Preston Hall an early hoice for the reception and treatment of potential asualties, and in the early days of September 1939 beginning was made in the erection of new hutments hich are now familiar throughout the country Within ix months the huts were completed and the first patients dmitted Side by side with the reception of civilian nd Service patients the sanatorium section of the hos-ital—though greatly curtailed in the number of beds vailable—continued to function and no administrative ifficulties have been experienced

---

[1] See *Lancet*, May 31, 1941, p 710

The association of a general hospital cheek by jowl ith a sanatorium is something new in medical organisa-ion in this country, and here again experience has shown that there is nothing incompatible in the association The routine of the village settlement has not been interfered with in any way The presence of a general hospital in the grounds of Preston Hall has in fact, done something to awake again in some of us a conscience in general medicine and surgery which a lifetime devoted to tuberculosis is apt to destroy and I believe I am speaking with the authority of my colleagues on the E M S staff when I say that they too have come to regard tuberculosis as a wider and more varied subject than they had never kown And that the two staffs can coöperate in the fullest measure was proved during the dark days following the evacuation of Dunkirk.

Preston Hall Kent J B McDOUGALL,
Medical Director

McARTHUR HERNIOPLASTY

SIR,—May I be allowed to join issue with Squadron-Leader McLaughlin (*Lancet*, July 5, p 11) on the value of the McArthur operation for inguinal hernia which he describes and practises as a routine procedure ? I have used it in selected cases in the past nine years as a compromise between the Bassini and the Gallie operations, but I find the indications becoming less frequent I do not agree that the anatomy of the inguinal canal is not disturbed by this procedure In fact, in order to make the short strip of fascia last until the internal ring is reached there is a temptation to pull firmly on each stitch and the distortion thereby produced is often more marked than in the Bassini operation. Certainly Gallie did not intend fascial strips to be used in this way, but to be darned loosely over the gap

In young active patients such as those with whom Squadron-Leader McLaughlin is dealing, the musculo-aponeurotic arch which surgeons call the conjoined tendon is well developed except where the hernia is unusually large Any suturing of this muscle, whether with catgut silk or fascia must cause it to atrophy. I have seen a direct hernia actually produced in this way where no hernia previously existed, the surgeon believing that he was " strengthening the inguinal canal by a few Bassini sutures In this type of patient, Kocher's operation, in which the sac is invaginated into itself and brought out near the anterior superior iliac spine, is undoubtedly the best because it is based on a physiological conception and strictly respectsthe conjoined tendon The second step of the operation is important and significant The sutures which reef the external oblique aponeurosis from above downwards narrow the inguinal canal thus relaxing and splinting the stretched muscular fibres of the conjoined tendon in the same way as a shoulder abduction splint relaxes a paralysed deltoid The operation is a simple one and should take no longer than ten minutes It was taught to me by Mr J H Rawlinson of the Northern Hospital Liverpool about nine years ago, and since then I have used it 288 times in 680 inguinal hernias with increasing confidence and without modifying it in any detail

Nor can I support Squadron-Leader McLaughlin's claim that the McArthur operation permits the patient to return to full duty in five weeks In dock labourers this practice would be disastrous The longer the patient abstains from heavy work the better, whatever the operation and a great deal of disability will be avoided if the surgeon insists on this point

Weaverham Cheshire J A MARTINEZ

SUPPRESSION OF URINE IN CRUSH ŒDEMA

SIR —The appearance among air-raid casualties of this syndrome—crush œdema followed by suppression of urine—stimulates one to survey all the conditions which are in any way comparable in the hope of finding some guide in treatment The paper by Mr Patey and Dr Robertson in THE LANCET of June 21 in which it is suggested that the symptoms may be mitigated by controlling the leak of fluid which takes place suddenly out of the circulation into the injured limb brings to mind work which was done many years ago by A W. Sellards on Asiatic cholera in Manila (Principles of Acidosis Harvard Press 1917) Sellards describes the suppression of urine which occurs in cholera when the patient collapses because of the huge effusion of fluid from the circulation into the intestine This suppression is associated with acidosis and he found that large doses of bicarbonate given intravenously was the most useful form of therapy He emphasised that this treatment should be started as soon as possible in the early stages of collapse in cholera, but found that it was possible sometimes to restart the secretion of urine by intravenous bicarbonate even when suppression had been present for two days He indicated that it was advisable to include calcium in the solution but necessary to avoid an excess of sodium He laid stress on the importance of noting the reaction of the urine frequently, as it was not permissible to use massive injections of alkali intravenously after the urine had become alkaline

Edinburgh. H RUSSELL.

ENTEROBIUS AND EXCRETA

SIR,—Threadworm infestation appears to be on the increase in this country In your issue of Dec 28 1940 Sir Philip Manson-Bahr recommended phenothiazine in doses of 4 g or more daily, and diphenan (B D H) is held to prevent the reproductive cycle of the parasite In China the disease is widespread through the insanitary habits of the people, who save their excreta in Shanghai jars mix them with water and bail out the infected contents on the vegetables in their gardens Recent reports of numerous infestations in this district led me to make enquiries among the smallholders, and in one morning I spoke to two lettuce growers who admitted following the Chinese practice with small modifications. I hope local health officers will take note

PAIN IN ACUTE APPENDICITIS

SIR —Mr Ruscoe Clarke and Mr Shapiro have done well to call attention to the indubitable fact that pain is not invariably the first symptom in cases of appendicitis It is encouraging to find the rising school of clinicians testing and qualifying the dogmatic statements of former teachers Nevertheless the fact that pain is generally the first symptom of appendicitis still holds good, and it is probable that those who first taught this merely overemphasised the fact in order to call attention to its great importance

London W 1 V. ZACHARY COPE

ST JOHN OPHTHALMIC HOSPITAL, JERUSALEM —The report of this hospital for 1940 shows that work, despite war conditions, was heavier than ever There were 926 inpatients, an increase of 234 over the previous year, and almost 200,000 attendances in the outpatients department The work on the new south block has been proceeding satisfactorily, and the Order of St John has offered it to the government of Palestine for the duration of the war to be used as a civilian-casualty hospital

SERVICE CASUALTIES —Surgeon Lieutenant Duncan Lorimer, M.B Edin , R.N V R , H.M S *Jersey*, and P/T/Surgeon Lieutenant A. K. Beardshaw, M B Sheff , R N V R , H.M S Yacht *Fiong* are reported missing, presumed killed.—Lieutenant R M Solomon M R C S , R.A.M C , has been posted as missing, believed prisoner of war

SOVIET WAR SURGERY —On Friday, July 25 at 7 30 P M , at 11 Chandos Street, London, W 1, Dr Janet Vaughan and Mr Ruscoe Clarke will speak on Some Soviet Contributions to War Surgery Invitation cards may be had from the Society for Cultural Relations with the U S S R , 98, Gower Street, W C 1 observation of the behaviour of individual personalities—if this term be still appropriate—for a reasonable period of time after they have left hospital Your contributors of July 5 did not do this The desire to be the first in Britain to rush into print must provide their principal excuse, since such pioneer work has already been carried out abroad on a larger scale by Moniz, Freeman and others One fact clearly emerges the new procedure injures severely the frontal lobes, a part of the brain which giants of the past such as Ferrier, Hitzig, Flechsig and Bianchi—to name but a few at random—considered to be of the greatest functional importance in the higher mammals, an opinion which is supported by thorough and careful workers of today like German, Jacobsen, Brickner and Rylander Incidentally Jacobsen has provided evidence of the specificity of function of the prefrontal lobes, so that it is unlikely that their function can be taken over by other cerebral areas after their liquidation

If, then, the frontal lobes be an essential part of the highest mental level, derangement of which, as Hughlings Jackson long ago suggested, is the first stage of dissolution in mental disorder, it is evident that any benefit derived from their destruction is at the expense of certain mental functions, attributes and potentialities which can never be restored The frontal lobes in such cases must still have been functioning in some fashion intermediate between normality and complete failure, because no benefit accrues from the destruction of centres which have already ceased to function The "cured" individual has dropped a rung on the evolutionary ladder I am not denying that such descent may seem a desirable alternative to incurable mental disorder Indeed, in a well-organised world of the future a new subhuman species may have its uses as hewers of wood and drawers of water Moreover, in certain individuals this highest level may never have been well developed and so its loss will not be severely felt I must, however, beseech the leucotomy experts to hold their hand as long as possible in dealing with mental patients formerly of great intellectual strength, delicate and sensitive minds or high moral or spiritual attributes, and be content to assist Nature's well-tried healing powers

Finally the employment of this method in the neuroses appears to me to be absolutely indefensible and can only be regarded as a measure of the lack of human sympathy and understanding and psychotherapeutic insufficiency of those who carry it out

Friern Hospital, N 11 C R BIRNIE

FUTURE OF GENERAL PRACTICE

SIR,—I am glad to have the assurance of Sir Farquhar Buzzard that I have misunderstood the principles of the Nuffield Trust, but the probable effect which the proposed changes will have on the lives of the patients and doctors of the future is a matter on which opinions are likely to differ, and after reading once again the article on the work of the trust in THE LANCET for Feb 1 I am still not convinced that it will be an organisation which will "come back to the individual man, be quickened by the individual life and respect individual autonomy to the fullest possible extent"

In terms of practical administration the point at issue resolves into the degree to which centralisation should be carried out in the hospital service, in the interest of the patients served and of the doctors supplying the service The Nuffield Trust proposes a form of organisation in which there will be a small number of very highly specialised and efficient hospitals working in association with a large number of other hospitals of inferior status I suggest that it would be a better plan to have a large number of general hospitals of approximately equal standing scattered throughout the country Is there any good reason why Bangor, for instance, should not have a good general hospital? It is the seat of a University College and the cultural and business centre for the counties of Caernarvon and Anglesey with a population of nearly 200,000 people This population should support a hospital of 1000 beds There might be a similar hospital at Wrexham or some other convenient town in North Wales It will be objected that there are not enough men of consultant rank to staff such hospitals If this is true at present it is because of the
unorganised state of postgraduate instruction It is no
due to any lack of natural ability in the doctors N
doubt much of the medical work done in England an
Wales falls short of the best standards This is
condition which we hope to remedy Much of the ba
surgery occurs because men with natural aptitude hav
not had adequate training in their special subject whil
men lacking in natural talent have had econom
advantages in early life which have enabled them
enter the ranks of the consultants With a rational ar
correlated system of postgraduate teaching, includi
opportunities for practical work under graduated sup
vision, there would be no difficulty in training up a bo
of consultants large enough for all the needs of t
community It is my opinion that the scheme of t
Nuffield Trust will not produce such a desirable resu

It is perhaps only fair to point out that although t
plan I have indicated would give enormously increas
opportunities to the general body of the members of
profession it would reduce the monopoly value of t
services of the consultants and specialists

Liverpool HENRY H MACWILLIAM

VILLAGE SETTLEMENTS IN WAR-TIME

SIR,—There were some who at the outbreak of w
thought that the entire fabric of village settleme
organisation would fall to the ground owing to t
impracticability of selling products in days when gover
ment requirements must take first place Expo
markets for goods—a prominent feature of prew
Papworth and Preston Hall—would certainly
eliminated to a large extent, and the question at on
arose Could the modern village settlements surv
in a period when luxury articles and the staple produc
of the industries could be manufactured only by gover
ment permits ? If not, the only course would be f
these institutions to close down for the period of th
war and endeavour to accommodate settlers in wo
in the near neighbourhood of the villages

War was in itself a challenge to village settlemen
to rearrange and reorganise themselves to meet ne
conditions The ways and means by which the man
difficulties have been overcome cannot be detailed here
but it can be said with truth that the industrial section
at both Papworth and Preston Hall have never bee
busier at any previous time in their history The chang
has indeed been remarkable The turnover at Presto
Hall has more than doubled in just over fifteen month
and, by the simple expedient of acquiring more machiner
and erecting more buildings and employing more outsid
workers, the turnover could be increased to four or fiv
times that of the peace-time figure of £100,000 or so a yea

Obviously it has been impossible to increase th
volume of work done without healthy labour being calle
upon to help, for the extra labour could not possibly
recruited and trained entirely from the tuberculo
population passing through the institutions At Presto
Hall outside labour has been called in, but only to
limited degree, and my object in reporting on the prese
position of village settlements is to issue a warning
this very direction If the village settlement conceptio
is to remain, there must be a limit to the number
outside healthy people employed in industries the temp
of which is adjusted to the needs of the tuberculo
patients The tendency to expand the purely industri
aspect of the settlement must never be allowed to pr
judice the main function of the settlement itself, whic
is the care and treatment of the tuberculous Onc
the balance of man-power has passed from the tuberc
lous to the healthy, then all the most valuable attribut
of the tuberculosis settlement disappear Adherence
this principle may have limited the industrial turnov
at Preston Hall, but it has preserved the integrity of
scheme which has been successful for the past fifteen year

My fear is that in an attempt to produce goods and
increase industrial income the very scheme which ha
taken so many years to build up may be sabotage
Let there be growth, but let the growth be in accordan
with the principles laid down by the late director an
founder of Papworth, by the reports of the employme
committee of the Joint Tuberculosis Council and b
others who have studied such schemes from the
inception If, however, the industrial mechanism
settlements has worked smoothly during the war, the

have been special problems in other directions to solve At the outbreak of hostilities only one of the better-known settlements was requisitioned, in part at least by the Emergency Medical Service Its geographical position near Maidstone made Preston Hall an early choice for the reception and treatment of potential casualties, and in the early days of September, 1939, a beginning was made in the erection of new hutments which are now familiar throughout the country Within six months the huts were completed and the first patients admitted Side by side with the reception of civilian and Service patients the sanatorium section of the hospital—though greatly curtailed in the number of beds available—continued to function, and no administrative difficulties have been experienced

The association of a general hospital cheek by jowl with a sanatorium is something new in medical organisation in this country, and here again experience has shown that there is nothing incompatible in the association The routine of the village settlement has not been interfered with in any way The presence of a general hospital in the grounds of Preston Hall has, in fact, done something to awake again in some of us a conscience in general medicine and surgery which a lifetime devoted to tuberculosis is apt to destroy, and I believe I am speaking with the authority of my colleagues on the E M S staff when I say that they too have come to regard tuberculosis as a wider and more varied subject than they had never kown And that the two staffs can cooperate in the fullest measure was proved during the dark days following the evacuation of Dunkirk

J B McDOUGALL,
Medical Director

Preston Hall, Kent

McARTHUR HERNIOPLASTY

SIR,—May I be allowed to join issue with Squadron-Leader McLaughlin (*Lancet*, July 5, p 11) on the value of the McArthur operation for inguinal hernia which he describes and practises as a routine procedure ? I have used it in selected cases in the past nine years as a compromise between the Bassini and the Gallie operations, but I find the indications becoming less frequent I do not agree that the anatomy of the inguinal canal is not disturbed by this procedure In fact, in order to make the short strip of fascia last until the internal ring is reached there is a temptation to pull firmly on each stitch, and the distortion thereby produced is often more marked than in the Bassini operation Certainly Gallie did not intend fascial strips to be used in this way, but to be darned loosely over the gap

In young active patients, such as those with whom Squadron-Leader McLaughlin is dealing, the musculo-aponeurotic arch which surgeons call the conjoined tendon is well developed except where the hernia is unusually large Any suturing of this muscle, whether with catgut, silk or fascia, must cause it to atrophy I have seen a direct hernia actually produced in this way where no hernia previously existed, the surgeon believing that he was " strengthening " the inguinal canal by a few Bassini sutures In this type of patient, Kocher's operation, in which the sac is invaginated into itself and brought out near the anterior superior iliac spine, is undoubtedly the best because it is based on a physiological conception and strictly respectsthe conjoined tendon The second step of the operation is important and significant The sutures which reef the external oblique aponeurosis from above downwards narrow the inguinal canal, thus relaxing and splinting the stretched muscular fibres of the conjoined tendon in the same way as a shoulder abduction splint relaxes a paralysed deltoid The operation is a simple one and should take no longer than ten minutes It was taught to me by Mr J H Rawlinson, of the Northern Hospital, Liverpool, about nine years ago, and since then I have used it 288 times in 680 inguinal hernias with increasing confidence and without modifying it in any detail

Nor can I support Squadron-Leader McLaughlin's claim that the McArthur operation permits the patient to return to full duty in five weeks In dock labourers this practice would be disastrous The longer the patient abstains from heavy work the better, whatever the operation, and a great deal of disability will be avoided if the surgeon insists on this point

WILLIAM HENRY WILLCOX

KCIE, CB, CMG, MD LOND, FRCP, FIC

The passing of Sir William Willcox on July 8 leaves a gap in medicine which will be difficult to fill Trained first as a chemist and later in medicine, he used his double qualification to advance clinical medicine and to make contact with its sister professions Having taken the London B Sc in 1892 he entered St Mary's three years later with a natural science scholarship, qualifying M B with gold medal in forensic medicine and other honours in 1900 Then followed a period of struggle for he had little private means and no influential backing, but he made ends meet by private coaching and a lectureship in chemistry until in 1907 he was elected to the staff as outpatient physician About this time A P Luff resigned his appointment as junior analyst to the Home Office and Willcox succeeded him, working with Sir Thomas Stevenson and on his death succeeding to the senior position He handled with success many *causes célèbres*, and by his brilliant identification of hyoscine in mortal remains preserved, by the murderer's fatal slip, with quicklime was instrumental with Sir Bernard Spilsbury in bringing "Dr" Crippen to justice In the early part of the last war he was sent to Mudros where typhoid and dysentery had befallen the casualties from Gallipoli, and later went to Mesopotamia as consulting physician to the Forces with the temporary rank of colonel, when his services in combating scurvy and beriberi were recognised with high distinctions Returning to London after the war he reluctantly gave up his Home Office appointment and devoted himself more to clinical medicine From 1919 to 1935 he was physician to St Mary's and enjoyed a large consulting practice But the Home Office retained him as medical adviser until his death The wealth of his knowledge and experience was revealed in his study of toxic jaundice embodied in the Lumleian lectures of 1931 published in our columns, and in the rheumatic affections he became a recognised authority

Walter Stoneman

Willcox was slow of speech and thought He never made a step forward until he was sure that the foundations were well and truly laid Those who did not know him were apt to underrate his ability until they found themselves caught out by it He did everything which lay in his power for the hospital he loved and for generations of its students, many of whom he helped in a tight corner In the early years of the century when the medical school was not yet financially prosperous he gave much of his time to teaching, holding lectureships in chemistry, physics, hygiene, forensic medicine and chemical pathology, and later in medicine He was a regular attender at meetings and committees of a number of learned societies, over four of which he was elected to preside, discussion always interested him and he never spoke without careful preparation of his subject In 1935–36 he was master of the Society of Apothecaries Slow to form opinions he stuck to them when reached with the tenacity of honest conviction Those who did not share his views admitted their genuine quality and agreed that "Wilks" was a prodigious worker An hour after midnight was the best time to catch him on the phone, but he was to be seen riding in the Park before breakfast This was his recreation and he was never happier than with his horses or on the hunting field He liked dining out and was hospitable at home He was just the same to rich and poor and was beloved by the sisters and nurses of his wards

Sir William Willcox was the son of William Willcox of Melton Mowbray He married Mildred, eldest daughter of W Griffin of Clapton, Northants, and leaves his widow with three sons and a daughter

FRANK GEORGE LAYTON

MRCS, JP

Through the death of Dr F G Layton on July Walsall has lost a citizen and a doctor His work life was spent in and about back streets, and long bef it began he wandered in and out of the homes of t poor with his father who was essentially a poor ma parson Born at Hounslow in 1872 he was educated at King's College School and *qualified from* St Thomas's Hospital in 1894 House-appointments at St Thomas's, the Brompton, and Great Ormond Street gave him a good general background before he went as assistant surgeon to Walsall General Hospital He remained to practise medicine and humanity in the town, and became honorary physician to the hospital, town councillor and magistrate He felt keenly the civic responsibilities of the doctor and he was sure that the doctor's train experience and knowledge of men and women w badly needed in the council chamber and the co room Dr Layton's record of service shows that practised what he preached and some of his m valuable work was done as chairman of the juve court His life was never leisured yet he always fo time for the things he wanted to do, and writing one of them "Dr Grey" was published in 19 "Sable and Motley," "The Old Doctor," and "Beh the Night Bell" were among the novels that follow These shrewd commentaries, full of lively dialog described the life of a panel practitioner Though author emerges as a lovable character the descript would probably have displeased him He also wr several plays Miss Horniman produced "The Pa Pump" in London, Manchester and Birmingham, his most successful play for children was called " Land of Make Believe"

EDMUND TYTLER BURKE

DSO, MB GLASG, LIEUT-COLONEL RAMC (RETD

News of the death on June 14 of Colonel Burke cause much regret in the wide circle of those at ho and abroad who knew him through his vigorous writi on venereal diseases, and has come as a shock to friends in the North and in London, including b students and postgradua who benefited from his tea ing These will remem him for his easy friendlin his enthusiasm and for encouragement he gave to who sought his advice views, expressed with cla and vigour, on certain n lected aspects of his subj led at times to dissensions which he proved a dough opponent and more than a to hold his own Unf tunately, in later years, activities were restricted failing health and he *obliged in March last to res* his appointment as director of the Whitechapel Cli But he had been able to complete and publish a textb embodying his great experience which should l remain a standard work

Colonel Burke was the son of W M Burke, chamberlain of Dundee He was educated at Pe St Andrews and Glasgow, graduating in 1914 when already held a commission in the R A M C (S R) served in Gallipoli and Mesopotamia where he command the 40th field ambulance and was later A D M S No Persia He left the Army in 1920 to become V officer in Salford with a teaching appointment Manchester University Two years ago he came so

FOUR PHASES OF BIRTH*

SIR JOSEPH BARCROFT, M.A. Camb., F.R.S.

UNTIL the last two or three years little has been added to the meagre knowledge of the physiology of birth possessed by our forefathers. This may seem strange, for each of us depends for our very existence on its successful negotiation. Millions have died who might conceivably have lived, given greater knowledge on the part of the responsible people. Yet there are reasons for the want of progress; at any particular birth the attention of those concerned is completely and rightly concentrated on the effort to get that individual child into the world as satisfactorily as possible and they have little opportunity for observation and less for experiment. What I shall say towards the more accurate description of birth falls under four headings:

1. Birth might be described as a change in the atmosphere in which the fœtus lives: the external atmosphere, that with which its skin is in contact, and the internal atmosphere, which for our purpose is essentially that to which its brain is subjected.

2. At birth a considerable volume of blood seems to be transferred from the placenta to the fœtus. I shall discuss the reasons which account for an excessive quantity of blood being in the fœtal circulation just before birth, the extent of the plethora, why the redundant blood is transferred to the neonatal organism and its fate when it gets there.

3. The change in conditions means that on birth the blood must acquire its oxygen from the air instead of from the placenta; therefore, on birth, a great quantity of blood must be circulated through the lung. Up to birth, on the other hand, the pulmonary circulation is functionally redundant and is actually short-circuited.

4. There is the all important subject of the first breath.

THE CHANGE IN ATMOSPHERE

The external environment of fœtal life is the amniotic fluid and this presents the minimum of contrast to the fœtus itself. The composition of the amniotic fluid is not unlike that of the body fluids of the fœtus; the temperature of the amniotic fluid does not differ materially from that of the embryo. For these reasons, even though the sensory nerve-endings of the mature skin are capable of abundant stimulation little in the way of stimuli pass their way. We have no exact knowledge of degree of excitation of the fœtal cutaneous nerves, but in the absence of direct knowledge we have interesting information of a secondary character; we have evidence of happenings in the embryo, presumably reflexes, of which the cutaneous sensory nerves form the afferent paths. Fig. 1 is a tracing of the electric variations in the muscle of a fœtus. The fœtus (preserving its relation with the placenta) was alternately in a bath of saline at its own temperature, and in the air above; these changes simulated in a crude way the alteration in the external environment which takes place at birth. Each spike in the tracing represents the contraction of a muscle-fibre in the region adjacent to the electrodes which picked up the current. When the fœtus was in the salt solution no muscular fibres were contracting; once the fœtus was lifted into the air, abundant contraction took place. In fewer words, the existence or otherwise of muscular tone was largely dependent on a tempest of stimuli from the skin, which stimuli do not occur when the embryo is in an isotonic fluid medium at the fœtal temperature.

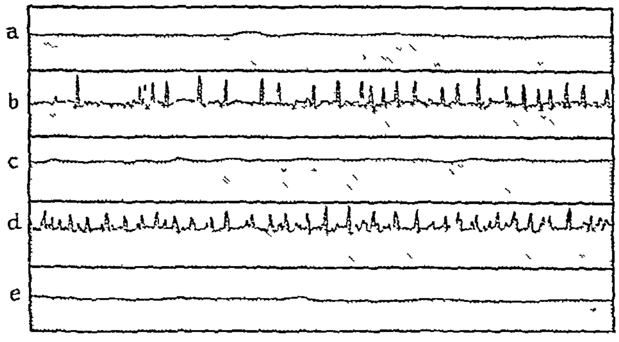

FIG. 1.—Record of muscular tone in fœtus of sheep at 144 days. Respiration maintained through umbilical cord. a, c, e, fœtus in bath; b, d, fœtus out of bath.

Our knowledge of the internal environment chiefly concerns oxygen. The fœtus (I allude principally to its brain) has an oxygen supply adequate for existence, but not adequate for sustained effort; after it is born it has an oxygen supply adequate for both. As some criterion of the adequacy of an oxygen supply it may be said roughly that if the organism can undergo any sustained exertion without lowering the oxygen content of its arterial blood the supply is adequate; if, on the other hand, the arterial blood blackens when the creature exercises its muscles with the activity of which they are capable—that is, if the oxygen in the arterial blood falls in exercise—not only are the contracting muscles and heart faced with the prospect of oxygen debt but the brain is faced with a "blackout." For example, no athlete by running can alter the normal bright red colour of his arterial blood; but I have seen the blood of an extremely fit person go dark and his face become intensely cyanosed at an altitude of 15,000 feet, when he undertook mild pedalling exercise on an ergometer. The same is true of animals suffering from experimental pneumonia due to poison gas, and indeed in cases of chlorine poisoning. Applying this yard-stick to the fœtus, the answer is unambiguous; it may be questioned whether the blood of the embryo at birth is oxygenated even up to the standard that would suffice for what would be normal resting conditions in a born animal. The blood of the carotid artery contains only about half the amount of oxygen which it is capable of carrying. Such a concentration of oxygen in man would be incompatible with clear thought and possibly even with consciousness, but not incompatible with the inhibition of random movements and with reflexes of a lower order.

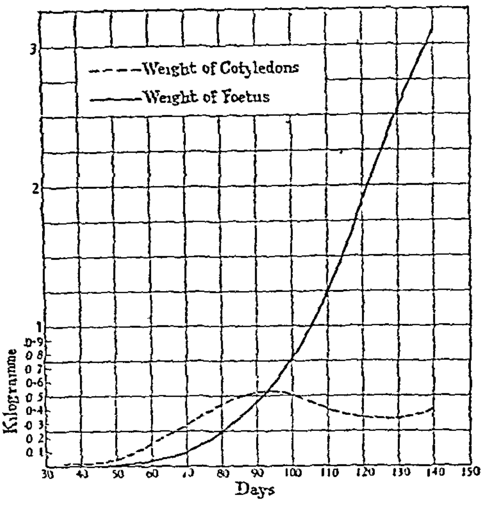

FIG. 2.

How comes this very restricted prenatal oxygen supply? It is caused by the needs of a rapidly growing fœtus outrunning the relatively fixed possibilities which exist of its obtaining oxygen from its mother. The capillary systems of the two bloods are in close juxtaposition in the placenta and the oxygen diffuses from that of the mother to that of the fœtus, through the intervening tissue. Inquiry into the conditions for such diffusion elicits some surprising facts. First, the placenta (in the sheep, at least) reaches its maximum weight not at the end of pregnancy, when the fœtus makes its greatest demands, but after the elapse of only about two-thirds of the whole period of gestation. The period in the sheep is 147 days, and the placenta is at its maximum weight at about the 100th day (fig. 2). The fœtus at the 100th day is quite small, perhaps one-eighth

---

* Abstract of the Sharpey Schafer lecture given at the University of Edinburgh on Feb. 28.

Medical Research Council of Ireland

The *council has made a whole time grant to* Dr Cecil Mushatt, and grants in aid to Dr James Deeny, Mr D K Malley and Mr J G Waugh The grants of Dr T E T Bradshaw and Prof Hans Sachs have been renewed

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on July 7, with Mr Roy Young, the president, in the chair, Dr Archibald McPhater (Bowmore, Islay) and Dr Herbert Pinkerton (Glasgow) were admitted to the fellowship

Medical Honour

The M B E has been awarded to Dr L F Togneri, a ship's surgeon in the Merchant Navy

Medical Society for the Study of Venereal Diseases

The annual general meeting of this society will be held on Saturday, July 26, at 2 15 P M, at 11 Chandos Street, London, W 1 At 3 P M, Colonel L W Harrison, the president, will open a discussion on the present trend of incidence of venereal diseases in England and Wales and the methods of control Dr Margaret Rorke, Lieut Colonel T E Osmond, Dr Letitia Fairfield, Surgeon Commander David Duncan, Surgeon Lieutenant Genevieve Rewcastle, and Wing-Commander J M Kilpatrick will also speak

London Chest Hospital

Lieut -Colonel Henry Guest, M P, presiding on July 8 at the annual meeting of this hospital, said that despite severe damage in recent air raids the hospital had now been reopened for inpatients and all departments had resumed working The building had begun of a new pathological department to replace the one that had been completely destroyed, burying records and specimens representing 90 years of research on chest affections

Diphtheria Immunisation

The number of children under school age who have been immunised against diphtheria remains dangerously low in all but a few districts of Scotland The returns of inoculations received by the Department of Health show that efforts *to secure the immunisation of children have so far been* mainly concentrated on school children But as the age of maximal susceptibility to diphtheria is 1–4 years and case mortality is then highest, the department have issued a circular urging that immunisation should be carried out as soon as possible after a child reaches the age 9–12 months Inoculation at that age will practically ensure the child's safety until he enters school when a further inoculation is advisable As most schools have now been closed for summer holidays local authorities are asked to direct the attention of their medical staffs and of general practitioners to the immunisation of the pre school group of children Every effort should be made to induce parents to bring forward young children for inoculation during the remaining summer weeks in order to safeguard them from attack by diphtheria during the winter

In Birmingham Dr H P Newsholme, the medical officer of health, lately told a press reporter that in the first six months of this year there were 600 accurate diagnoses of diphtheria in the city compared with 336 last year, and 56 deaths compared with 16 in the corresponding period of 1940 Dr Vera Fellowes, assistant medical officer for diphtheria immunisation and maternity and child welfare in Birmingham, added "it is all so silly when immunisation is all that is needed and is so simple" To allow for the three months before it becomes effective immunisation should be done at once to safeguard children for next winter

---

Lord Horder has been appointed personal adviser to the Minister of Food on medical aspects of food problems

---

GLAXO Laboratories Ltd inform us that 5 mg and 25 mg ampoules of their Berin injection (aneurine hydrochloride B P) will take the place of the 2 mg and 10 mg ampoules now in use, while 3 mg Berin tablets as well as 1 mg tablets will be available in future

CORRIGENDA —The annotation on page 46 of THE LANCET of July 12 gives the impression that sulphamidothiazole (Cibazol or Ciba 3714) is a new sulphonamide, whereas these are, of course, other names for sulphathiazole —For "only 18 months having elapsed since the first operation was done" (*Lancet*, July 5, p 7, col 1, line 6) read "7 months"

Appointments

ORMEROD, F C, M D Manc, F R C S aural surgeon to t Westminster Hospital

Infectious Disease in England and Wales

WEEK ENDED JULY 5

Notifications —The following cases of infectious dise were notified during the week smallpox, 0, sca fever, 787, whooping-cough, 5316, diphtheria, 7 paratyphoid, 140 (Stoke-on-Trent 40, Liverpool 2 typhoid, 46, measles (excluding rubella), 6524, pn monia (primary or influenzal), 680, puerperal pyre 159, cerebrospinal fever, 201 (County of London, Manchester, 13, Birmingham and Sheffield, each 8), po myelitis, 12, polio-encephalitis, 2, encephalitis leth gica, 1, dysentery, 61, ophthalmia neonatorum, No case of cholera, plague or typhus fever was noti during the week

During the six weeks ended July 5 the cases of cerebrosp fever notified in England and Wales numbered in successive we 254, 244 236, 211 192 and 201 The course of the diseas the first half of 1941 has been similar to that in 1940 except the initial rise this year was *more gradual, and the* maxim was about a third lower and occurred a week earlier There approximately 9183 notifications in the first half of 1940 and in the first half of 1941

In Scotland in the six weeks ended July 5 the numbers been 56, 47 42 50, 54 and 51 *The maximum in 1940* wa week earlier, and in 1941 a week later, than in England and W The numbers of notifications in the first half of 1940 were and 1661 in the corresponding period in 1941

The number of civilian and service sick in the Infectious Hospi *of the London County Council* on July 2 was *1452*, inclu scarlet fever, 160 diphtheria 276, measles 252, whooping co 423, enteritis 23 chicken pox, 65 erysipelas 34 mumps poliomyelitis, 1 dysentery 3, cerebrospinal fever, 43, puerp sepsis 7, enteric fevers, 12, german measles, 9, other dise (non infectious), 65, *not* yet diagnosed, 73

Deaths —In 126 great towns there was no death fr scarlet fever, 3 (0) from enteric fever, 28 (3) fr whooping-cough, 5 (1) from measles, 25 (1) fr diphtheria, 32 (2) from diarrhœa and enteritis un 2 years, and 6 (0) from influenza The figures parentheses are those for London itself

Enfield Willesden and Birmingham each reported a *fatal* of enteric fever

The number of stillbirths notified during the week 208 (corresponding to a rate of 40 per thousand t births), including 18 in London

Infectious Disease in England and Wales

WEEK ENDED JULY 5

Notifications —The following cases of infectious di were notified during the week smallpox, 0, sc fever, 787, whooping-cough, 5316, diphtheria, paratyphoid, 140 (Stoke-on-Trent 40, Liverpool typhoid, 46, measles (excluding rubella), 6524, p monia (primary or influenzal), 680, puerperal pyr 159, cerebrospinal fever, 201 (County of London, Manchester, 13, Birmingham and Sheffield, each 8), p myelitis, 12, polio-encephalitis, 2, encephalitis le gica, 1, dysentery, 61, ophthalmia neonatorum, No case of cholera, plague or typhus fever was not during the week

During the six weeks ended July 5 the cases of cerebro fever notified in England and Wales numbered in successive 254, 244 236, 211, 192 and 201 The course of the dise the first half of 1941 has been similar to that in 1940 except the initial rise this year was more gradual, and the max was about a third lower and occurred a week earlier There approximately 9183 notifications in the first half of 1940 and in the first half of 1941

In Scotland in the six weeks ended July 5 the numbers been 56, 47, 42, 50, 54 and 51 The maximum in 1940 week earlier, and in 1941 a week later, than in England and The numbers of notifications in the first half of 1940 were and 1661 in the corresponding period in 1941

The number of civilian and service sick in the Infectious Hos of the London County Council on July 2 was 1452, inc scarlet fever 160, diphtheria, 276, measles 252, whooping 423, enteritis 23, chicken-pox, 65 erysipelas, 34, mump poliomyelitis, 1, dysentery, 3, cerebrospinal fever, 43 pue sepsis, 7, enteric fevers, 12, german measles, 9, other di (non infectious), 65, not yet diagnosed, 73

Deaths —In 126 great towns there was no death scarlet fever, 3 (0) from enteric fever, 28 (3) whooping-cough, 5 (1) from measles, 25 (1) diphtheria, 32 (2) from diarrhœa and enteritis 2 years, and 6 (0) from influenza The figure parentheses are those for London itself

Enfield, Willesden and Birmingham each reported a fatal of enteric fever

The number of stillbirths notified during the week 208 (corresponding to a rate of 40 per thousand births), including 18 in London

FOUR PHASES OF BIRTH *

SIR JOSEPH BARCROFT, M A Camb , F R S

UNTIL the last two or three years little has been added to the meagre knowledge of the physiology of birth possessed by our forefathers This may seem strange, for each of us depends for our very existence on its successful negotiation Millions have died who might conceivably have lived, given greater knowledge on the part of the responsible people Yet there are reasons for the want of progress, at any particular birth the attention of those concerned is completely and rightly concentrated on the effort to get that individual child into the world as satisfactorily as possible and they have little opportunity for observation and less for experiment What I shall say towards the more accurate description of birth falls under four headings

1 Birth might be described as a change in the atmosphere in which the fœtus lives the external atmosphere, that with which its skin is in contact, and the internal atmosphere, which for our purpose is essentially that to which its brain is subjected

2 At birth a considerable volume of blood seems to be transferred from the placenta to the fœtus I shall discuss the reasons which account for an excessive quantity of blood being in the fœtal circulation just before birth, the extent of the plethora, why the redundant blood is transferred to the neonatal organism and its fate when it gets there

3 The change in conditions means that on birth the blood must acquire its oxygen from the air instead of from the placenta, therefore, on birth, a great quantity of blood must be circulated through the lung Up to birth, on the other hand, the pulmonary circulation is functionally redundant and is actually short-circuited

4 There is the all important subject of the first breath

THE CHANGE IN ATMOSPHERE

The external environment of fœtal life is the amniotic fluid and this presents the minimum of contrast to the fœtus itself The composition of the amniotic fluid is not unlike that of the body fluids of the fœtus, the temperature of the amniotic fluid does not differ materially from that of the embryo For these reasons, even though the sensory nerve-endings of the mature skin are capable of abundant stimulation little in the way of stimuli pass their way We have no exact knowledge of degree of excitation of the fœtal cutaneous nerves, but in the absence of direct knowledge we have interesting information of a secondary character, we have evidence of happenings in the embryo, presumably reflexes, of which the cutaneous sensory nerves form the afferent paths Fig 1 is a tracing of the electric variations in the muscle of a fœtus The fœtus (preserving its relation with the placenta) was alternately in a bath of saline at its own temperature, and in the air above, these changes simulated in a crude way the alteration in the external environment which takes place at birth Each spike in the tracing represents the contraction of a muscle-fibre in the region adjacent to the electrodes which picked up the current When the fœtus was in the salt solution no muscular fibres were contracting, once the fœtus was lifted into the air, abundant contraction took place In fewer words, the existence or otherwise of muscular tone was largely dependent on a tempest of stimuli from the skin, which stimuli do not occur when the embryo is in an isotonic fluid medium at the fœtal temperature

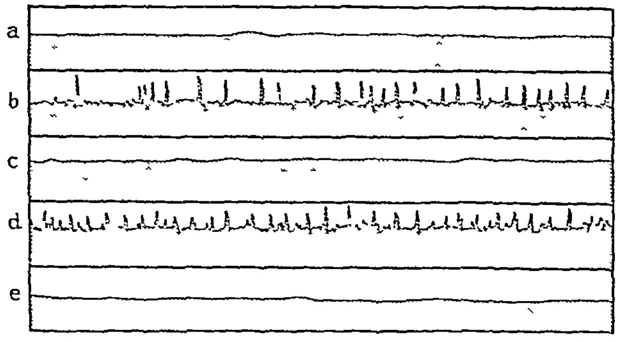

FIG 1—Record of muscular tone in fœtus of sheep at 144 days Respiration maintained through umbilical cord a, c, e, fœtus in bath, b, d, fœtus out of bath

Our knowledge of the internal environment chiefly concerns oxygen The fœtus (I allude principally to its brain) has an oxygen supply adequate for existence but not adequate for sustained effort, after it is born it has an oxygen supply adequate for both As some criterion of the adequacy of an oxygen supply it may be said roughly that if the organism can undergo any sustained exertion without lowering the oxygen content of its arterial blood the supply is adequate, if, on the other hand, the arterial blood blackens when the creature exercises its muscles with the activity of which they are capable—that is if the oxygen in the arterial blood falls in exercise—*not only* are the contracting muscles and heart faced with the prospect of oxygen debt but the brain is faced with a “ blackout ” For example, no athlete by running can alter the normal bright red colour of his arterial blood, but I have seen the blood of an extremely fit person go dark and his face become intensely cyanosed at an altitude of 15,000 feet, when he undertook mild pedalling exercise on an ergometer The same is true of animals suffering from experimental pneumonia due to poison gas, and indeed in cases of chlorine poisoning Applying this yard-stick to the fœtus, the answer is *unambiguous* it may be questioned whether the blood of the embryo at birth is oxygenated even up to the standard that would suffice for what would be normal resting conditions in a born animal The blood of the carotid artery contains only about half the amount of oxygen which it is capable of carrying Such a concentration of oxygen in man would be incompatible with clear thought and possibly even with consciousness, but not incompatible with the inhibition of random movements and with reflexes of a lower order

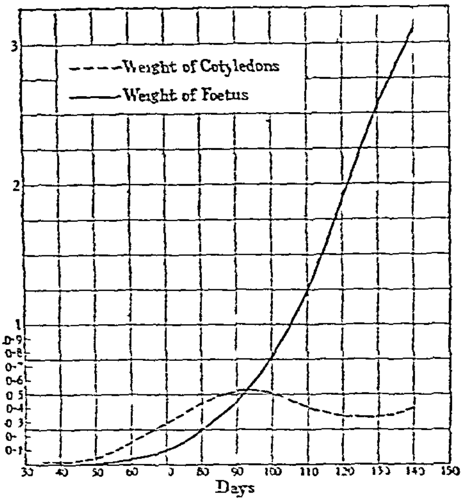

FIG 2

How comes this very restricted prenatal oxygen supply? It is caused by the needs of a rapidly growing fœtus outrunning the relatively fixed possibilities which exist of its obtaining oxygen from its mother. The capillary systems of the two bloods are in close juxtaposition in the placenta and the oxygen diffuses from that of the mother to that of the fœtus through the intervening tissue Inquiry into the conditions for such diffusion elicits some surprising facts First, the placenta (in the sheep, at least) reaches its maximum weight not at the end of pregnancy, when the fœtus makes its greatest demands, but after the elapse of only about two-thirds of the whole period of gestation The period in the sheep is 147 days, and the placenta is at its maximum weight at about the 100th day (fig 2) The fœtus at the 100th day is quite small, perhaps one-eighth of its size at birth Secondly, the quantity of blood in the placenta at any one time does not increase appreciably during the last third of pregnancy The volume of the fœtal capillary bed in the placenta remains more or less constant during this period yet the total quantity of blood in the fœtal circulation increases about six-fold (fig 3) It is as though a grown man had a lung no larger, and containing no more blood, than that of a year-old infant

---

* Abstract of the Sharpey Schafer lecture given at the University of Edinburgh on Feb 28

The placental bed at 100 days is much larger than is necessary for the fœtus of that age—in short, the placenta is organised ahead of its immediate utility But why is a still larger placental bed not required for the full-grown fœtus? The problem is emphasised when we turn from the volume of blood in the placenta to the quantity which runs through it per minute

F B = Vol of fœtal blood traversing placenta of sheep per min (c cm)

Age (days)	F B	Age (days)	F B
111	111	137	568
126	218	138	284
127	162	152	300
129	600		

Till about a fortnight before birth the volume of the stream keeps up with the growth of the fœtus, so that an ever-increasing flow is forced through a bed of almost constant size This is possible because of the rise of arterial pressure, on the 76th day the pressure in the umbilical artery exceeds that in the umbilical vein by less than 10 mm of mercury, on the 138th day the difference is about 40 mm —a four-fold increase in the driving force A week or two before birth the stream is at its maximum and in the last fortnight or so nature resorts to one further device to improve oxygen transport a sharp rise in hæmoglobin (fig 4)

The provision for an adequate oxygen supply to the fœtus may, in respect of time, be divided into three stages the growth of the placental bed, up till the 100th day, the increase of fœtal arterial pressure, mainly after the 100th day till about the 130th day, and the increase of hæmoglobin in the last fortnight Yet in spite of all these mechanisms the position is always deteriorating The provision which at 100 days was more than good enough for the fœtal needs is by the 147th only just sufficient, even after it has been exploited in every way At the 80th day, and for a considerable time after that, the fœtus is living at what I may call the high alpine level, its carotid blood is oxygenated about as completely as that of a person living at 15,000 feet (roughly the summit of Mont Blanc), by 130 days it has passed the Andean level, and reached that of the Himalayas, at birth it is under Everest conditions, perhaps even more stringent ones The fœtus, as it grows to maturity, suffers, like the mountaineer, from an increasing degree of oxygen want, unlike the mountaineer, it cannot meet that situation by panting How far it can be said to acclimatise is not known, but at all events the experience of the alpinist, so far from being novel, is one to which he was subjected in his mother's womb

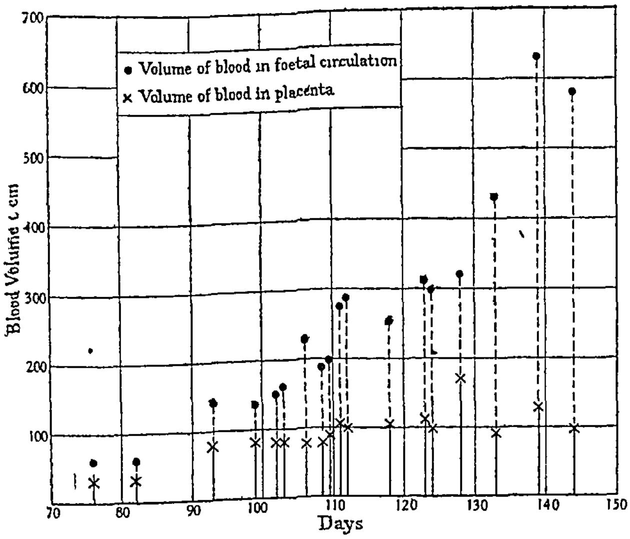

FIG 3

Within four minutes of birth all this is changed I well remember the joy with which I ran down the Peak of Teneriffe, prompted by the exhilaration of the inhalation of continually increasing quantities of oxygen, yet it took me about half an hour to get down to 5000 feet The fœtus makes its descent—a fa greater one—within four or five minutes, as was shown b a continuous record of the oxygen in its arterial blood as i was subjected to cæsarean section Before birth it i doubtful whether the fœtal brain was capable of consciousness, even if there were anything to be conscious of during birth the fœtus must have undergone a positiv blackout, yet in but a few minutes the lamb is fully conscious and in a few more it can get up and walk

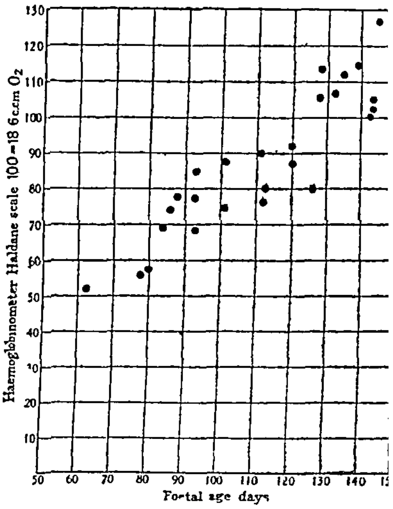

FIG 4

TRANSFER OF BLOOD FROM THE PLACENTA AT BIRTH

We have seen that for some weeks before birth the fœtal vessels had held 100–150 c cm of blood At birth most of this is transferred to the fœtus, presumably by contraction of the umbilical and placental vessels, in the sheep, at all events, with its cotyledonous placenta, the increased muscular tone of the uterus has, I imagine, little effect on the fœtal circulation Two sets of lambs of comparable weight may be compared in respect of their blood-volume (Barcroft and Gotsev 1937)—first, those naturally born and within a few hours of birth, secondly, those born at term by cæsarean section, the cord being tied as rapidly and with as little interference to the placenta and to the lamb as possible Here are three such comparisons

BLOOD VOLUME IN C CM PER KG

	Lambs naturally born	Lambs born by rapid cæsarean section
	168	153
	161	119
	168	108
Mean	166	127

The naturally born lambs had the advantage to the extent of 39 c cm of blood per kg It is fair to say that the estimation is much more easy in the naturally born lamb, which probably accounts for the figures being more uniform But even it it be granted that 39 c cm per kg —or about 110–120 c cm in all—is an over estimate, half that figure would mean a great deal of blood to a lamb—more than 10% of its whole blood volume

When the cord is tied near the umbilicus in a cæsarean section, a considerable pressure rapidly develops in the umbilical vessels This is due to their muscular walls contracting down on the blood If incisions be made in the vessel walls near the ligature blood gushes and it is easy to collect it in a measuring cylinder Three such experiments gave 75 c cm, 83 c cm and 80 c cm Judging from the pressure at which this blood is forced out, it seems unlikely that less is expelled into the fœtus during a normal birth

Why should the greater part of the blood in the placenta be transferred to the lamb at birth? An easy reply would be that as the placenta goes out of action the lung comes in, and that whichever organ of respiration is used, be it the placenta or the lung, the blood is necessary for it, but it is not certain that this simple explanation covers the facts It has yet to be proved that the fœtal lung is deficient in blood , the blood may not be circulating at a great rate but we know nothing really about the amount of blood in the fœtal lung except that the lung looks pretty vascular even in the embryo One reason why more blood may be wanted by the lamb than by the fœtus is that many abdominal organs, which have not functioned to any great extent in fœtal life, now become functional and presumably require blood

What casts doubt on all the above hypotheses is the fate of the blood after it arrives in the lamb Gotsev (1939) found in 2 out of 3 lambs that about 10% of the hæmoglobin with which they were born disappeared from the circulation , as far as we know it is broken down, the hæmatin portion being partly excreted as bilirubin and the iron stored in the liver Why overload the lamb's circulation with corpuscles that are at once to be broken down and perhaps give rise in exaggerated cases to icterus neonatorum ? For the sake of the iron Bunge many years ago called attention to the limited store of iron available to the baby during the months of suckling The initial store which is conferred on it at birth seems to be set aside against the day, which soon comes, on which iron is wanted for the formation of fresh hæmoglobin, and indeed for many cell enzymes into the bargain

ALTERATIONS IN THE THORACIC CIRCULATION

After birth each complete circuit of the blood consists of alternate phases, through the systemic and pulmonary circulations respectively In the fœtus such a sequence would be functionally redundant There is no point in driving masses of blood through a lung in which no exchange of gases takes place, therefore in the fœtus the lung is short-circuited Yet as soon as the fœtus is launched on the world the lung must function The greatest economy will clearly be attained in a system which provides for the most efficient short-circuiting before birth compatible with the least possible degree of short-circuiting immediately birth takes place

There are in the fœtus two by-passes , if blood passes through either of these, it will evade the lung The first is the foramen ovale, in the septum between the right and left auricles Blood arriving in the right auricle can pass through the foramen ovale into the left auricle, thence to the left ventricle and on to the aorta, thus cutting out the lung The second by-pass is the ductus arteriosus springing from the pulmonary trunk and entering the aorta just beyond the aortic arch Blood reaching the right side of the heart can pass to the right ventricle, up the pulmonary trunk, and through the ductus arteriosus to the dorsal aorta The blood which reaches the systemic system by this route cannot go to all parts of the body it cannot go to the head, the arms, the coronary system or any vessel springing from the aortic arch , it can only go to the vessels supplied by the dorsal aorta Both these by-passes have medical importance, because one or other may remain patent with corresponding prejudice to the circulation Probably because it is rarely seen in the dissecting-room except as represented by a strand of connective tissue, two erroneous ideas are prevalent about the ductus arteriosus First that it is small and that the foramen ovale is the important by-pass , and secondly that it closes by a process of cicatrisation taking weeks or months In an experiment carried out by my colleagues Dr A E Barclay, Dr D H Barron and Dr K J Franklin thorotrast was injected into the femoral artery of a rather decrepit fœtus , because of the low fœtal blood pressure it passed upwards against the stream, entered the aortic arch and the ductus arteriosus An X-ray cinema film showed that the bore of the ductus is at least as large as that of the dorsal aorta

Has any particular corpuscle on reaching the right side of the heart the same chance as any other corpuscle of passing through a particular by-pass ? One school holds that all the blood reaching the right side of the heart from whatever source becomes thoroughly mixed in the right auricle, the other and older school holds that the blood reaching the heart via the inferior vena cava on the whole passes through the foramen ovale, and so to the aortic arch, while that arriving from the superior vena cava passes into the right ventricle and up the pulmonary trunk and thence either through the ductus to the dorsal aorta or through the lung, but not along the aortic arch The implication in this second view affects the blood from the placenta which goes either directly or by way of the liver into the inferior vena cava and which therefore brings the heart the reddest blood reaching it ; this blood goes, with little admixture, through the foramen ovale to the left heart and the aortic arch, so that the organs supplied by the aortic arch have a first option on such oxygen, sugar and so on as reaches the circulation ; apart from the liver the organs in question are those which matter in fœtal life—the heart muscle, the brain, the thyroid and the thymus It is possible to judge between the two schools by the method of X-ray cinematography

If thorotrast is injected into the superior vena cava, the whole of the opaque material goes straight through the right auricle, into the right ventricle, and up through the pulmonary trunk , the stream there divides, part flowing through the ductus arteriosus into the dorsal aorta and the rest through the pulmonary arteries into the pulmonary circulation (fig 5A) No thorotrast appears on the left side of the heart or in the aortic arch until it has made the circuit of the lungs On the other hand, if the thorotrast is injected into the inferior vena cava the major part passes at once to the left side of the heart, presumably through the foramen ovale, and appears immediately in the aortic arch and brachiocephalic artery The minor part passes into the right side of the heart and up the pulmonary trunk The head therefore has a first call on the most oxygenated blood

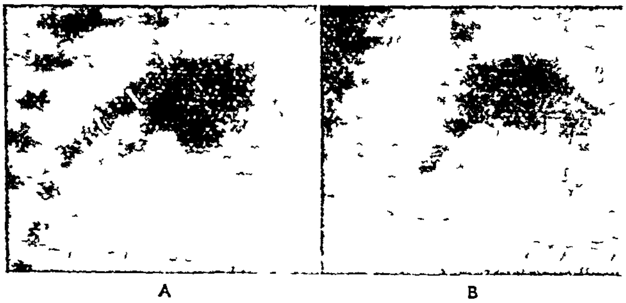

FIG 5—(A) Radiogram taken before ligation of the cord in the lamb , (B) taken 4 minutes after ligation of the cord In each case thorotrast has been injected into the superior vena cava giving a light shadow both in it and the right ventricle, and a dense shadow in the pulmonary trunk, the pulmonary artery, the ductus arteriosus and the dorsal aorta In (A) the junction of the ductus and the aortic arch can be seen at the lower margin of the rib The ends of the ductus are marked by two white lines In (B) the shadow extends into the pulmonary artery but not into the ductus or aorta

The closure of the ductus also has been investigated by Dr Barclay's X-ray cinema Cæsarean section was performed in the sheep, which and the following facts were revealed At delivery, and indeed for a short time after it, the ductus remains fully open, but when the umbilical cord is tied the picture rapidly changes , within 4 minutes the ductus is completely closed, or at least is closed to the point at which the lumen admits of no stream large enough to cast a shadow (fig 5B) It may, as far as we know, never reopen, or it may oscillate for a while between absolute closure and trivial patency, but it never allows more than a nominal quantity of blood to pass The time relations of the closure are those of a sphincter such as the cardiac sphincter of the stomach and not those of a cicatrisation These time relations are consistent with the structure of the ductus, which differs from the neighbouring arterial wall , the muscle of the sphincter is there for anyone with a microscope to see and nerve-endings may be seen in it In fact the sphincter is part of the vasomotor system The physiological occlusion as time goes on is followed by a conversion of the muscle into connective tissue

A different method is needed to investigate closure of the foramen ovale If the blood in the left ventricle (and consequently in the carotid artery) is completely arterial—if the hæmoglobin is 100% oxyhæmoglobin and if there is no reduced hæmoglobin present—all that blood must come from the lung and none can come from the great veins through the foramen ovale This state is actually reached within 4 or 5 minutes of the ligature of the umbilical cord if the fœtus is breathing an atmosphere of oxygen (Barcroft, Kramer and Millikan 1939) Thus the foramen ovale must close within the same period

The X rays give us what little information we have about which is the first to close, the ductus arteriosus or the foramen ovale.

Lipiodol was injected into the inferior vena cava of a newly born lamb, it divided into a major and a minor stream, the *former passing to the left side of the heart through the* foramen ovale, the latter into the right side The first stream soon ceased, which seemed to show that the foramen ovale had closed, all the lipiodol now went into the right ventricle and was seen to traverse the ductus, so reaching the dorsal aorta Finally the path was diverted again and all the lipiodol went into the pulmonary circulation

So far as this single experiment can be trusted, the sequence of shutting is first the foramen ovale, second the ductus arteriosus In any case, after 5 minutes, almost the whole venous inflow (apart from the pulmonary veins) seems to go through the lung before it reaches the left side of the heart

THE FIRST BREATH

There is a paradox about the first breath as there is about the maiden voyage of a steamship That voyage is the initiation of the functional life of the vessel, in this sense it is the initial effort of the steamer, but behind it is a background of trial trips, assemblage of parts, fitting of machinery and all the rest So it is with the first breath, true, it is the first time that air is taken into the lungs, if only because the fœtus has never been exposed to air, but the movements responsible for that inhalation have a history which can be traced back to the very first efforts of which the fœtus was capable

That first effort is a simple reflex (Barcroft and Barron 1939), it appears on the 34th day of fœtal life in the sheep. If the embryo at that time is sharply tapped under the eye it will turn its head, with the nose towards the side on which it is struck No other skin area will elicit a movement, no other movement takes place when the locality in question is struck Actually the locality is the skin area covering the point to which the maxillary branch of the fifth cranial nerve has grown The whole functional nervous system is then a single reflex arc, with the maxillary branch of the fifth nerve as its receptor, a neuron which involves the reticular formation in the medulla as its cell station and the efferent fibres which supply certain neck muscles as the effector This functional nervous system spreads as the days of gestation go by, about a week later four things have taken place (Barcroft 1939) a much gentler stimulus will elicit *movement*, the skin area, stimulation of which will produce movement, is much greater and notably involves the nose to which the fifth nerve has now grown, the muscles involved in the response are so numerous as to transform the simple movement into a spasm, and the response is not merely one spasm but a rhythm consisting of perhaps twenty spasms, each of which looks like a little gasp

By the 49th day the mechanism has become so delicate that only with difficulty can the fœtus be held still enough to preclude the development of these rhythmic spasmodic efforts Both the extent and the frequency of the rhythm depend on the severity of the stimulus, a gentle stimulus will cause only rhythmic contraction of the respiratory muscles—the diaphragm, the intercostals and the laryngeal muscles—while a strong stimulus will elicit a more rapid rhythm and one which extends to a great part of the body The first spasm in the response to a strong stimulus has properties which are not repeated in those which follow. If the fœtus is on its side it will turn its head crown upward, throw it back and with its feet make a complex movement which looks like a crude effort to get up, the whole procedure indeed closely resembles the first effort to rise made by the lamb There is then sometimes a slight pause and the subsequent movements are of the rhythmic type which we have seen in younger fœtuses The whole syndrome presents the appearance of an effort to get up followed by a fit of breathlessness Thus even a third of the way through pregnancy the essential neuromuscular mechanism has been laid down, and as it were tried out Not the least remarkable feature of these spasmodic rhythms of the respiratory type is their relation to asphyxia So far from asphyxia being able to stimula them, the reverse is the case, asphyxia has no oth action than that of a depressant, and in time wou extinguish them entirely

Between the 50th and 60th day *the activities of t* embryo undergo a remarkable change Instead being so active that the slightest touch or moveme starts a burst of rhythmic activity, it is now almo inert At first *sight it conveys* the impression of bei moribund, and doubtless for this reason its late activities have not been more fully realised, for thou a number of observers have described movements of respiratory type in embryos their significance has n hitherto been grasped If the healthy fœtus of 60 da gives the impression of lacking the power of movemen there are three ways of waking it up by asphyxi by exposure, and by appropriate surgical section the brain

The new development which is responsible for t quiescence of the 60-day fœtus is the appearance inhibition, this is due to the grip exerted on the low portions of the brain by a centre at a higher level T secret of asphyxia is that it depresses this seat of gover ment and liberates the lower centres from its dominio In effect then the rôle played by asphyxia is functionall to convert the 60-day embryo into one of 50 day Exposure acts in a similar way

The general position, geographically, occupied by t inhibitory centre is revealed by surgical procedur Dr Barron has succeeded in transecting the centr nervous system in fœtuses of 50–80 days without inte fering with their growth or affecting the date at whi they are born A fœtus in which section has been do half way up the forebrain has, like one subjected to small degree of asphyxia, lost its inhibition and exhibit a rhythm of the respiratory type on the smallest provocation

During the last two-thirds of the gestation period there is, then, a constant battle between the warring element of the fœtal brain, the lower part of which is tending to give movement—respiratory movement at that—and the upper part of which is all for quiet, and the upper part normally wins during gestation

There are other important forces which must not be lost sight of They are on the side of movement, and during intra-uterine life are in abeyance These are the sensory impulses caused by stimulation of peri pheral nerves, and among them the fifth cranial nerve—that which initiated the first movement—always holds a special place As long as the fœtus is in the amniotic fluid the peripheral impulses do not come into action or come in only to a slight extent because there is so little in the environment to excite them The effect of wholesale peripheral stimulation, however, would be to raise the sensitivity of the brain and so give it a bias towards action These then are the forces marshalled on the two sides for quiescence the inhibitory mechanism, for movement accidental stimuli from the nose, mouth, skin or muscles reaching a brain of exalted sensitivity, exalted by the general mass of peripheral stimuli

In that setting the lamb appears The inhibition of the fœtus is abolished or reduced by the suspension of the placental circulation, stimulation inevitably occurs and is amplified, as it were, by the heightened sensitivity of the nervous system Then response takes place That response is the old movement developed 100 days previously in the embryo, which is now no longer a spasmodic movement in a fluid medium but a gasp which expands and draws air into the lungs, it is the first breath

SUMMARY

During the latter half of the period of gestation in the sheep the quantity of fœtal blood in the placenta remains relatively constant, while that in the fœtus increases with the growth of the placenta as much as 6–8 times The growing needs of the fœtus are met, in the placenta, by an increased rapidity of blood flow and by increasing quantities of hæmoglobin in the blood

A considerable volume of the fœtal blood circulating in the placenta is transferred to the fœtus at birth The excess of corpuscles is broken down and the iron is stored

Evidence is given of the functional closing of the foramen ovale and the ductus arteriosus within a few minutes of birth

Evidence is also given showing that the essential neuromuscular mechanism for drawing the first breath is laid down between the 34th and the 50th day of gestation, and that asphyxia, far from stimulating the early spasmodic rhythms of the respiratory type, actually depresses them At this stage exposure or asphyxia excite no activity in the embryo

By the 60th day of gestation higher levels of the brain have developed sufficiently to inhibit the lower centres , so that the 60-day fœtus appears much more inert than the active 50-day fœtus Asphyxia depresses the higher centres and liberates the lower centres, thus converting the inert 60-day fœtus functionally to the active 50-day fœtus Exposure has the same effect

At birth the lamb experiences both partial asphyxia —because of suspension of the placental circulation— and exposure It responds with the respiratory movement which it developed some 100 days before Sensory impulses from the skin heighten the tendency towards respiration

AMMONIA-GAS POISONING

FORTY-SEVEN CASES IN A LONDON SHELTER

Maxwell Caplin, M R C S

LATELY HOUSE OFFICER AT ST LEONARD'S HOSPITAL L C C

Early in September, 1940, during a heavy air-raid on London, a large brewery whose cellars were being used as a shelter received a direct hit from a bomb The damage to the building was not severe, but a fragment of flying metal pierced the connecting pipe of an ammonia ndenser in the corner of one of the cellars, and gaseous amonia was set free This spread rapidly through the owded shelter, and it was about ten minutes before employee of the brewery wearing an oxygen respirator as able to shut off the condenser

First-aid parties arrived almost at once and performed eir duties ably Most of those affected by the gas ere able to leave the building without help, but a few d to be brought out by the first-aid parties who entered e gas-filled cellars, some wearing civilian others civilian-ty respirators First-aid posts dealt with a large mber of cases, some of which were considered sufficiently rious to need hospital treatment

This account describes the signs, symptoms, treatment d subsequent course of some of the cases admitted St Leonard's Hospital In all, 75 cases were admitted, t owing to the rapid evacuation to base hospitals and e difficulty of obtaining case-notes after transfer, only 7, representing in the main the more serious cases, could e traced satisfactorily

CLINICAL FEATURES

Clinically, the patients could be divided into three ain types—mild, moderate and severe—depending on e extent of involvement of the respiratory tract he mild and moderate cases were mostly a considerable stance from the ammonia condenser at the time of the xplosion and were able to leave the shelter unaided hose in the severe group were resting near the condenser, nd were among the last to leave, many of them being so vercome as to need help from first-aid parties

Mild group —This comprised 9 patients with mild atarrhal symptoms, the inflammatory process being mited to the conjunctivæ and the upper respiratory assages The patients complained of a smarting ensation in the eyes and mouth, pain on swallowing, nd some of a tightness in the throat All were very oarse and could hardly raise their voices above a whiser Cough was not a prominent feature There was no shock or distress, the colour was good and the temperature and pulse-rate were not raised The conjunctivæ were suffused and there was swelling of the eyelids The lips, mouth and tongue were intensely reddened, dry and raw looking, and there was a strong smell of ammonia in the breath The fauces presented a similar picture with the addition of œdema No adventitious sounds were heard on auscultation of the chest

Moderate group —In this, the largest group, there were 27 cases who showed the effect of more severe or prolonged exposure to the gas Here, in addition to an exaggeration of the signs and symptoms present in the mild cases, there were moist sounds in the chest, suggestive of an extension of the inflammatory process to the bronchi and bronchioles There was smarting of the eyes, mouth and throat, together with a feeling of tightness in the chest, hoarseness and dysphagia Cough was prominent and productive of tenacious and, sometimes, blood-stained sputum There was no vomiting The colour was good, the pulse was strong and rapid, but the patient looked ill There was some restlessness with a slight increase in the respiration-rate, and in some the temperature was raised one or two degrees The conjunctivæ were hyperæmic and there was much lacrimation with swelling of the eyelids The lips, mouth, tongue and fauces resembled the picture seen in the mild type, but here œdema was more pronounced and there were dark red glazed patches scattered over the buccal mucosa indicating areas denuded of epithelium Auscultation of the chest revealed a poor air-entry with rhonchi, in some cases localised, and in others fairly generalised

Severe group —There were 11 cases in this group, exhibiting signs and symptoms of pulmonary œdema, evidence of still further extension of the inflammatory process to the lung parenchyma On admission they were shocked, restless and obviously distressed There was slight cyanosis, intense dyspnœa and persistent cough with much frothy sputum The pulse was rapid and of poor volume and the temperature was not raised The condition of the eyes, mouth and fauces was similar to that seen in the moderate cases The neck veins were not distended Generalised râles and rhonchi were audible in the chest

TREATMENT

The first aim was to combat shock and to relieve restlessness and dyspnœa in the severe cases , the second, to neutralise liquid ammonia present on the buccal mucosa, evidence of which was the strong ammoniacal smell in the breath , and the third, to relieve conjunctival and buccal pain All patients were put to bed, and in severe cases where shock and restlessness were present electric cradles were provided and morphia gr $\frac{1}{4}$–$\frac{1}{6}$ was given, the smaller dose where cyanosis and dyspnœa were evident Oxygen was administered by intranasal catheter to patients showing any sign of cyanosis Where moist sounds in the chest were pronounced, an injection of atropine gr $\frac{1}{100}$ was given and repeated two-hourly

The ammonia was neutralised with ordinary table vinegar, which was diluted one part in four with warm water and given as a mouth-wash and gargle After this, liquid paraffin was applied on a swab to soothe the roughened mucous membrane In the moderate and severe cases, where pain and œdema of the mouth and throat were more troublesome, a cocaine and adrenaline spray was used The eyes were irrigated with boric lotion and were instilled with a few drops of castor oil Cocaine was not used in the treatment of the eyes

SUBSEQUENT COURSE

Owing to the severity of the air-raids on London at that time, and the need to keep beds clear, rapid evacuation to base hospitals was essential, though the clinical condition of some of the patients would in normal times have made one doubt the wisdom of transfer The subsequent course of the transferred patients was gleaned from their case-notes which were made available to me after their discharge , I had no personal contact with these patients after they left St Leonard's Hospital

Mild group —The 9 cases in this group obtained considerable relief from the measures already outlined, and after a few hours' rest in bed they were fit for of the umbilical cord if the fœtus is breathing an atmosphere of oxygen (Barcroft, Kramer and Millikan 1939) Thus the foramen ovale must close within the same period

The X rays give us what little information we have about which is the first to close, the ductus arteriosus or the foramen ovale

Lipiodol was injected into the inferior vena cava of a newly born lamb , it divided into a major and a minor stream, the former passing to the left side of the heart through the foramen ovale, the latter into the right side The first stream soon ceased, which seemed to show that the foramen ovale had closed , all the lipiodol now went into the right ventricle and was seen to traverse the ductus, so reaching the dorsal aorta Finally the path was diverted again and all the lipiodol went into the pulmonary circulation

So far as this single experiment can be trusted, the sequence of shutting is first the foramen ovale, second the ductus arteriosus In any case, after 5 minutes, almost the whole venous inflow (apart from the pulmonary veins) seems to go through the lung before it reaches the left side of the heart

THE FIRST BREATH

There is a paradox about the first breath as there is about the maiden voyage of a steamship That voyage is the initiation of the functional life of the vessel , in this sense it is the initial effort of the steamer, but behind it is a background of trial trips, assemblage of parts, fitting of machinery and all the rest So it is with the first breath , true, it is the first time that air is taken into the lungs, if only because the fœtus has never been exposed to air , but the movements responsible for that inhalation have a history which can be traced back to the very first efforts of which the fœtus was capable

That first effort is a simple reflex (Barcroft and Barron 1939) , it appears on the 34th day of fœtal life in the sheep If the embryo at that time is sharply tapped under the eye it will turn its head, with the nose towards the side on which it is struck No other skin area will elicit a movement, no other movement takes place when the locality in question is struck Actually the locality is the skin area covering the point to which the maxillary branch of the fifth cranial nerve has grown The whole functional nervous system is then a single reflex arc, with the maxillary branch of the fifth nerve as its receptor, a neuron which involves the reticular formation in the medulla as its cell station and the efferent fibres which supply certain neck muscles as the effector This functional nervous system spreads as the days of gestation go by , about a week later four things have taken place (Barcroft 1939) a much gentler stimulus will elicit movement , the skin area, stimulation of which will produce movement, is much greater and notably involves the nose to which the fifth nerve has now grown , the muscles involved in the response are so numerous as to transform the simple movement into a spasm , and the response is not merely one spasm but a rhythm consisting of perhaps twenty spasms, each of which looks like a little gasp

By the 49th day the mechanism has become so delicate that only with difficulty can the fœtus be held still enough to preclude the development of these rhythmic spasmodic efforts Both the extent and the frequency of the rhythm depend on the severity of the stimulus , a gentle stimulus will cause only rhythmic contraction of the respiratory muscles—the diaphragm, the intercostals and the laryngeal muscles—while a strong stimulus will elicit a more rapid rhythm and one which extends to a great part of the body The first spasm in the response to a strong stimulus has properties which are not repeated in those which follow If the fœtus is on its side it will turn its head crown upward, throw it back and with its feet make a complex movement which looks like a crude effort to get up , the whole procedure indeed closely resembles the first effort to rise made by the lamb There is then sometimes a slight pause and the subsequent movements are of the rhythmic type which we have seen in younger fœtuses The whole syndrome presents the appearance of an effort to get up followed by a fit of breathlessness Thus even a third of the way through pregnancy the essential neuromuscular mechanism has been laid down, and as it were tried out Not the least remarkable feature of these spasmodic rhythms of the respiratory type is their relation to asphyxia So far from asphyxia being able to stimulate them, the reverse is the case , asphyxia has no other action than that of a depressant, and in time would extinguish them entirely

Between the 50th and 60th day the activities of the embryo undergo a remarkable change Instead of being so active that the slightest touch or movement starts a burst of rhythmic activity, it is now almost inert At first sight it conveys the impression of being moribund, and doubtless for this reason its latent activities have not been more fully realised , for though a number of observers have described movements of a respiratory type in embryos their significance has not hitherto been grasped If the healthy fœtus of 60 days gives the impression of lacking the power of movement there are three ways of waking it up by asphyxia by exposure , and by appropriate surgical section of the brain

The new development which is responsible for the quiescence of the 60–day fœtus is the appearance of inhibition , this is due to the grip exerted on the lower portions of the brain by a centre at a higher level The secret of asphyxia is that it depresses this seat of government and liberates the lower centres from its dominion In effect then the rôle played by asphyxia is functionally to convert the 60–day embryo into one of 50 days Exposure acts in a similar way

The general position, geographically, occupied by the inhibitory centre is revealed by surgical procedure Dr Barron has succeeded in transecting the central nervous system in fœtuses of 50–80 days without interfering with their growth or affecting the date at which they are born A fœtus in which section has been done half way up the forebrain has, like one subjected to a small degree of asphyxia, lost its inhibition and exhibits a rhythm of the respiratory type on the smallest provocation

During the last two-thirds of the gestation period there is, then, a constant battle between the warring elements of the fœtal brain, the lower part of which is tending to give movement—respiratory movement at that—and the upper part of which is all for quiet, and the upper part normally wins during gestation

There are other important forces which must not be lost sight of They are on the side of movement, and during intra-uterine life are in abeyance These are the sensory impulses caused by stimulation of peripheral nerves, and among them the fifth cranial nerve—that which initiated the first movement—always holds a special place As long as the fœtus is in the amniotic fluid the peripheral impulses do not come into action or come in only to a slight extent because there is so little in the environment to excite them The effect of wholesale peripheral stimulation, however, would be to raise the sensitivity of the brain and so give it a bias towards action These then are the forces marshalled on the two sides for quiescence the inhibitory mechanism , for movement accidental stimuli from the nose, mouth, skin or muscles reaching a brain of exalted sensitivity, exalted by the general mass of peripheral stimuli

In that setting the lamb appears The inhibition of the fœtus is abolished or reduced by the suspension of the placental circulation , stimulation inevitably occurs and is amplified, as it were, by the heightened sensitivity of the nervous system Then response takes place That response is the old movement developed 100 days previously in the embryo, which is now no longer a spasmodic movement in a fluid medium but a gasp which expands and draws air into the lungs , it is the first breath

SUMMARY

During the latter half of the period of gestation in the sheep the quantity of fœtal blood in the placenta remains relatively constant, while that in the fœtus increases with the growth of the placenta as much as 6–8 times The growing needs of the fœtus are met, in the placenta, by an increased rapidity of blood-flow and by increasing quantities of hæmoglobin in the blood

A considerable volume of the fœtal blood circulating in the placenta is transferred to the fœtus at birth The excess of corpuscles is broken down and the iron is stored

Evidence is given of the functional closing of the foramen ovale and the ductus arteriosus within a few minutes of birth

CALCIUM AND PHOSPHORUS STUDIES IN NORMAL PEOPLE

INCLUDING OLD AGE

J DOUGLAS ROBERTSON, M D , D Sc St And , D P H
CLINICAL CHEMICAL PATHOLOGIST TO THE MIDDLESEX HOSPITAL

(From the Courtauld Institute of Biochemistry)

As a preliminary to a series of observations on conditions associated with derangement of the calcium and phosphorus metabolism * a study was made of normal healthy adults

Serum calcium —The normal serum calcium is given by Peters and Van Slyke (1931) as 9–11 mg per 100 c cm in adults, and 10–11 5 mg per 100 c cm in children The circulating blood-cells are almost calcium free In a given person the serum calcium remains remarkably constant, thus Watchorn and McCance (1932) have shown that it does not vary throughout the day, and Clark (1920), Denis and Minot (1920), Mason (1921), and Bauer and Ropes (1926) showed that neither deprivation of calcium nor calcium-rich diets have any effect on the concentration of that substance in the serum Hjort (1925) was able to raise the serum calcium in dogs by giving calcium lactate in doses of 1 5 g per kg of body-weight in 5% solution—doses unlikely to be tolerated by human subjects

Serum inorganic phosphorus —Peters and Van Slyke (1931) have compiled a table from the reports of twenty-one authors in which they give the normal inorganic phosphorus as 2–5 mg per 100 c cm for adults, and 4–7 mg per 100 c cm for children The methods employed were those of Bloor (1918), Bell and Doisy (1920), Briggs (1923) and Tisdall (1922)

Serum phosphatase —The phosphatases are the enzymes which hydrolyse phosphate esters to liberate inorganic phosphate Different techniques are employed in the estimation of phosphatase with the result that the normal values vary widely according to the particular method employed The methods include those described by Kay (1930), Roberts (1930), Bodansky (1937), and King and Armstrong (1934)

Calcium and phosphorus balances —A comparison of the intake and output of calcium and phosphorus is a recognised method of determining the calcium and phosphorus metabolism of the body This method will recognise excessive calcium loss from the body long before osteoporosis of the skeleton begins It has now been established from observations in many laboratories that if normal healthy people live on a low intake of calcium, such as 0 1 g daily, then the body steadily loses calcium, chiefly in the fæces but also in the urine Sherman (1937) has calculated that if a 70 kg subject takes 0 45 g of calcium daily there is equilibrium between output and intake The figure of 0 45 g of calcium daily has come to be regarded by certain workers as the calcium requirement of the body, but this is not the case This figure represents the minimum of actual need, the optimum or ideal daily intake being about 1 g , with more during pregnancy and lactation

FINDINGS IN THE INQUIRY

Method —Throughout this series of investigations the serum calcium was estimated by Clark and Collip's (1925) modification of the method of Kramer and Tisdall (1921) The inorganic phosphorus was estimated by the method of Youngburg and Youngburg (1930), the serum being separated as quickly as possible from the cells and the estimation being carried out at once Serum phosphatase was determined by King and Armstrong's method (1934) The methods employed in the balance studies have already been reported by Beaumont, Dodds, and Robertson (1940)

Observations were made on the serum calcium, inorganic phosphorus, and phosphatase of 60 normal healthy people between the ages of twenty and forty (table I) In table II the serum-calcium findings in these 60 adults are compared with those already published by Watchorn and McCance (1932), Kramer and Tisdall (1921, 1922), Halverson, Mohler, and Bergeim (1917), Salvesen and Linder (1923), and Bogert and Plass (1923), amounting to 50 observations

Table III shows the results of analyses carried out on 15 people over sixty with an average age of 66 4 years In a previous publication Beaumont, Dodds, and Robertson (1940) reported on calcium and phosphorus balances in 9 normal healthy subjects aged nineteen to fifty-four, a modified table has been produced here showing the ranges of calcium and phosphorus excretion in these subjects on a low calcium intake and their negative balances in mg per kg (table IV) In the last column, using the total calcium output as the index, I have calculated the daily calcium maintenance per 70 kg of body-weight The mean figure of 0 31 g calcium daily is low On a low calcium intake the output no doubt becomes depressed below the normal equilibrium point I have tried to demonstrate this point in table V, in which the data here reported have been combined with 139 similar observations taken from papers by Bauer, Aub and Albright (1929), Von Wendt (1905), Sherman, Wheeler and Yates (1918), Sherman and Winters (1918), Sherman (1920), Rose (1920), Sherman, Gillett and Pope (1918), Sherman, Winters and Phillips (1919), Bogert and Kirkpatrick (1922), Hansman and Wilson (1934), and Beaumont, Dodds and Robertson (1940), the cases have been arranged into groups of increasing calcium intakes.

* Units of King and Armstrong † S D = Standard deviation

It seems to be widely believed, and has been stated by Harris (1941), that in middle age a large retention of calcium occurs In table VI the calcium excretion of adults over forty (mean age 52 1 years) and under forty (mean age 29 5 years) is compared The data have been obtained from the experiments of Bauer, Aub and Albright (1929), and Beaumont, Dodds and Robertson (1940) It will be seen that there is no difference between the calcium excretion of people over and under forty

DISCUSSION

Serum calcium, inorganic phosphorus and phosphatase in adults and old age —The range of serum calcium in normal healthy adults between twenty and forty was found to be 9 9–11 1, which is smaller than the accepted range The figure is similar to the findings in a series collected from the literature, differing from this series discharge They were typical of those who received treatment at the first-aid posts, and therefore of most of the gas casualties

---

* These observations will be reported in three further papers in THE LANCET The references for all four papers are given at the end of this one

Moderate group —Of the 27 cases in this group, 24 showed improvement after treatment, and these were evacuated ten and thirty hours after admission The 3 remaining cases showed great deterioration in their clinical condition and were detained at St Leonard's Hospital Within six hours of admission they became cyanosed, and dyspnœa and restlessness increased Clinically they resembled closely patients admitted with pulmonary œdema, and were treated in like manner In spite of treatment, their general condition gradually worsened, cyanosis and restlessness becoming still more severe Finally, they became comatose and died within thirty-six hours Post-mortem examination was not performed In 9 of the 24 patients who were evacuated, signs and symptoms of bronchopneumonia appeared on the second and third days All these cases received M & B 693 in addition to routine treatment, 6 recovered while the remaining 3 died within two days of the onset of symptoms An autopsy was done in 2 of these cases

Case A B —Male, aged 66 Mouth fauces, pharynx and larynx intensely inflamed Trachea and bronchi inflamed and filled with purulent exudate Lungs adhesions on both sides from old pleurisy Deeply congested lungs and patchy areas of bronchopneumonia Heart nothing abnormal

Case C D —Male, aged 47 Trachea and bronchi denuded of epithelium Lungs bronchopneumonia and pulmonary œdema

The remaining 15 patients made a relatively uninterrupted recovery, the average period in hospital being eight days. In most the conjunctivitis improved rapidly without further treatment, but in the more severe cases boric irrigations and castor-oil instillations were continued daily Severe corneal ulceration was noted in 2 patients In 12 cases at the Royal Free Hospital half were observed to have corneal ulceration on admission but this was not seen in those treated at St Leonard's Hospital where fluorescein was not instilled, so that corneal ulceration in mild degrees may have passed unnoticed Ulceration with slough formation inside the mouth was a common feature and responded rapidly to mouth-washes Hoarseness was persistent and was still present on discharge from hospital Laryngoscopic examination was not performed in these cases The bronchitis improved gradually and cleared, on the average, within seven days The mortality-rate in this moderate group of 27 cases was 22% Three cases died from what appeared to be delayed pulmonary œdema, and 3 from bronchopneumonia, though as the post-mortem evidence in one of these cases showed, pulmonary œdema was associated with the bronchopneumonia

Severe group —In this group 4 patients gradually went downhill They became more cyanosed and dyspnœic and died within forty-eight hours of admission The remaining 7 cases improved slightly under treatment and were transferred within ten hours of arrival to the base hospital Of these, 4 continued to improve and were discharged after an uneventful course about nine days later, and 3 became steadily worse and pursued a similar course to that of the patients in this group who were detained at St Leonard's Hospital They ultimately died within forty-eight hours of being transferred An autopsy was performed in two of these cases

Case E F —Female, aged 37 Mouth fauces, pharynx and larynx intensely injected and covered with purulent exudate Lungs both lower lobes show thin fibrinous exudate on pleural surfaces, bronchopneumonic areas in both lungs, and right upper lobe œdematous Heart nothing abnormal Liver somewhat enlarged and showing toxic degenerative changes, gall bladder normal Spleen slightly enlarged and softened Pancreas nothing abnormal Kidneys slightly toxic in appearance Stomach and intestines nothing abnormal Brain not examined

Case G H —Male, aged 19 Mouth fauces, pharynx and larynx injected, epiglottis covered by membrane of purulent exudate Trachea intense inflammation with much purulent exudate Lungs no exudate or fluid in pleural spaces, both lungs deeply congested, areas of broncho-pneumonic consolidation in lower lobes, upper lobes show no consolidation, and less congested, no evidence of tuberculosis or past lung disease Heart nothing abnormal Liver bright red, gall-bladder healthy Spleen congested but not hard Adrenals congested, no hæmorrhages Pancreas congested, no hæmorrhages Kidneys both congested Œsophagus nothing abnormal Stomach hyperæmia of summits of the mucous ridges Intestines healthy Brain not examined

Of the 11 cases in this group 7 died, representing a mortality of 63%

CONCLUSIONS

Although a number of casualty clearing stations might have been utilised, most of the cases were sent to St Leonard's Hospital This unequal distribution of casualties had two disadvantages First, the medical and nursing staff were overburdened It was not possible for 75 patients to be given the individual attention that could have been given to, say, 15, and no more than 15 need have been sent to this hospital if each casualty-clearing station in the area had received its proportion Secondly, because the casualty beds were filled, early evacuation had to be resorted to, in some cases earlier than good judgment would allow [1]

The effectiveness of the civilian respirators, both ordinary and duty, against gaseous ammonia was demonstrated by the first-aid personnel, who subsequently suffered no ill effects This experience was shared by those people in the shelter who put on their gas-masks at the first suspicion of gas A small proportion of the casualties had also worn their gas-masks, but these had felt much worse in them and taken them off They admitted coughing and spluttering before donning their masks, which suggests that they had already inhaled gas in some quantity In their pamphlet, "Air-Raid Precautions to be taken by Users of Ammonia" the Ministry of Home Security state

> "Tests have shown that any of the A R P respirators give a certain degree of protection against anhydrous ammonia gas, although they are not designed for the purpose"

In this series, morphia in doses of gr $\frac{1}{4}$–$\frac{1}{6}$ was given to all the shocked and restless patients There is no evidence that this measure was in any way connected with the development of bronchopneumonia

Three patients in the moderate group—cases in which, on admission, acute bronchitis was the essential respiratory lesion—developed the clinical picture of pulmonary œdema about six hours later This condition, therefore, may appear as a delayed event, altering the prognosis appreciably

SUMMARY

An account is given of 47 cases of ammonia gas poisoning resulting from leakage of a condenser into an air-raid shelter

The patients could be classified into mild, moderate and severe types In the mild type the main feature was acute pharyngitis and tracheitis, in the moderate, acute bronchitis, and in the severe, pulmonary œdema

Mild cases, of which there were 9, responded rapidly to treatment and were fit for discharge within a few hours

Of the 27 in the moderate group, 3 patients developed signs and symptoms of pulmonary œdema within six hours of admission and died, 9 developed bronchopneumonia on the second and third days and of these 3 died, 15 patients recovered completely apart from hoarseness, and were discharged after about eight days The fatality-rate for this group was 22%

The severe group contained 11 patients, 7 of whom underwent a rapid deterioration in their general condition and died within two days The other 4 patients made an uninterrupted recovery and were discharged from hospital after nine days The fatality-rate for this group was 63%

The civilian ordinary and duty respirators proved effective against ammonia gas

I wish to thank Dr Allen Daley for permission to publish this article and the medical officers of St Leonard's Hospital, the North Middlesex Hospital and Clare Hall Hospital, South Mimms, for their cooperation, and in particular Dr Arthur Morris and Mr E T Bailey, superintendent and deputy superintendent of St Leonard's Hospital

---

[1] Such difficulties were foreseen by Slot, G M J (*Lancet*, 1938, 2, 136) in his paper on casualties sustained in an explosion of ammonia gas in an ice cream factory

* Insufficient data   † Per 70 kg body weight

or any margin of safety, and thus represents a deficit for growing children and women during pregnancy and lactation In round figures, if the minimum calcium requirement is taken as 0 45 g daily then the optimum or ideal calcium requirement for a child is 1 g daily (obtainable in 1 quart of milk, Sherman 1937), for an adult at least 0 7 g daily (Sherman 1937), and for pregnant and lactating women 1 4–2 g daily (Coons 1935, Toverud and Toverud 1931, League of Nations Health Organisation Technical Commission on Nutrition, 1938)

Dietary consumption of calcium —The carefully compiled data of Sherman and Stiebeling (1936) in America, and of Orr (1937), Leitch (1937), and Crawford and Broadley (1938) in this country are in agreement that insufficient calcium is taken by large sections of the population If this applies in peace-time, how much more must it apply during war Most of our staple foods contain little or no calcium, so that it is possible to eat an abundantly nutritious yet calcium-poor diet Analyses of war diets at the present time show that if milk and cheese are excluded the average calcium content is only 0 2 g daily Green vegetables are known to be useful carriers of calcium but their high calcium content does not necessarily mean a high calcium absorption Thus spinach, which contains 0 078 g % of calcium, supplies the body with scarcely any of that mineral because of its oxalic acid content (Finke and Sherman 1935) There is a danger of serious calcium insufficiency in the population unless adequate amounts of milk or cheese or both are taken, or calcium is added in some form It was this danger of calcium deprivation which no doubt decided the Government to fortify with calcium a staple and cheap food such as bread The consumption of bread is high, and by its enrichment with calcium it would be possible for all classes to obtain an optimum amount of calcium

SUMMARY

In 60 normal healthy adults between the ages of twenty and forty years the mean serum calcium was 10 4 mg, the inorganic phosphorus 3 8 mg and the phosphatase 7 2 units (King and Armstrong), the ranges in that order being 9 9–11 1, 3 1–4 8, and 3 5–13 5

In 15 healthy people aged sixty to seventy-eight, the serum calcium and inorganic phosphorus were not found to be significantly different from those of younger adults The serum phosphatase was slightly raised in these older people, which may or may not be significant

A study was made of 9 normal subjects (33 observations) On a calcium intake of 0 1 g daily all subjects were in a negative balance, there was a total calcium excretion of 4 4 mg, and a negative calcium balance of 2 5 mg per kg of body-weight daily On a phosphorus intake of 0 37 g daily all subjects were in a negative balance, there was a total phosphorus excretion of 10 4 mg, and a negative phosphorus balance of 3 5 mg per kg of body-weight daily. The point at which equilibrium between intake and output of calcium took place was 0 45 g daily for a 70 kg subject This intake of calcium is usually referred to as the minimum or maintenance requirement of the body

It is important to distinguish between the intake of calcium which just produces equilibrium and that which allows for some retention Retention of calcium is necessary to maintain health, and essential to children and to women during pregnancy and lactation

If diets are to contain ideal amounts of calcium, adequate amounts of milk, cheese or both must be included If this is not possible then additional calcium ought to be taken

The calcium metabolism of middle age is no different from that of young adults

I wish to thank Prof E C Dodds for his criticisms, and the honorary staff of the Middlesex Hospital for permission to investigate their cases, quoted in the other papers in this series

Continued at foot of next page

only in having a slightly higher mean and slightly smaller range.

Calculated according to Fisher's "P" test (Fisher 1938) the difference between the serum calcium and inorganic phosphorus of adults aged twenty to forty and of those over sixty is of no significance (for calcium, P > 0 3, and for inorganic phosphorus P > 0 10) The higher mean serum phosphatase in old adults may possibly be of significance (P > 0 05)

TABLE II—COMPARISON OF THE FINDINGS SHOWN IN TABLE I WITH 50 OBSERVATIONS FROM THE LITERATURE

No of cases	Mean serum calcium	Range of serum calcium	Standard deviation
	mg /100 c cm		
60	10 39	9 9–11 1	0 27
50	10 06	9 3–10 8	0 37

Calcium and phosphorus balances and calcium requirements—In the 9 normal healthy adults on a low calcium intake of about 0 1 g daily the output of calcium was found to be consistently greater than the intake (table IV) The daily excretion of calcium averaged 4 4 mg per kg of body-weight and the daily negative balance 2 5 mg per kg, the corresponding figures for phosphorus being 10 4 mg and 3 5 mg With the lower calcium intakes of 0 038, 0 088, 0 116, 0 138, 0 185, 0 206, and 0 25 g daily the calcium output (corrected to a body-weight of 70 kg), although greater than the intake, was restricted This depression below the point at which calcium equilibrium could actually be maintained was greatest with the lowest calcium intake A constant calcium output was reached when the calcium intake rose to 0 28 g daily (0 384 g corrected to a body-weight of 70 kg) In carrying out experiments designed to determine the calcium requirements of the body there seems to be a certain level of calcium intake below which the calcium output does not give a true indication of the amount required for calcium equilibrium This critical level appears to be in the region of 0 38 g daily for a body-weight of 70 kg Approximate equilibrium between intake and output took place on a daily intake of 0 44–0 45 g when corrected to a body-weight of 70 kg The requirement for calcium equilibrium was therefore in the region of 0 45 g calcium daily It seems reasonable to expect that a minimum requirement would exceed the equilibrium requirement, but in the literature these terms are used synonymously

A comprehensive survey of this subject has been made by Leitch (1937) based on a study of almost 400 balances with daily calcium intake varying from 0 08 to 0 742 g Her series comprised 318 negative and 79 positive balances Positive balances were obtained on as low an intake as 0 196 g daily and negative balances on as high an intake as 0 65 g daily The numbers of negative and positive balances equalled one another with a daily intake of 0 50–0 55 g, and she concluded that the true daily maintenance requirement for calcium in her series was 0 55 g This agrees well with Sherman's (1921) estimate and is similar to Owen's (1939) figure for older men

It is abundantly clear from the experimental work of competent authorities that children require a surplus of calcium so that they may store or retain it at the rate of not less than 0 01 g per kg of body-weight daily Failure to do this in childhood adversely affects growth, weight, maturity, powers of reproduction, onset of senescence, and the health of the next generation (Sherman and Campbell 1924, Sherman and MacLeod 1925, Sherman and Booher 1931, Campbell, Bessey and Sherman 1935) When adult life is reached the body does not store calcium above its daily optimum intake except during pregnancy and lactation, or when it is deficient in calcium Much that is irrelevant has lately been written about the dangers of calcium overdosage Overdosage cannot exist among the adult population because the healthy body rejects in the fæces whatever calcium it does not require If children need to store calcium, what of adults nearing or over middle age? There is no evidence at all that middle-aged people behave differently from young adults in respect to their calcium metabolism Large retention of calcium is a peculiarity of growing children only, and a necessary one

Optimum calcium intake—The ideal calcium requirement for health is much greater than the minimum calcium requirement, with which it must not be confused At all times the body steadily loses calcium, but on a low calcium intake the loss is greater than the intake If the calcium is gradually increased a stage is reached when the intake equals the output, this intake is known as the "minimum calcium requirement," but more exactly might be termed "the calcium equilibrium intake" It is doubtful if this amount of calcium is even a true equilibrium requirement Observations on the intake and output of calcium are carried out in hospitals and clinics under ideal experimental conditions and with balanced diets In the home, where balanced diets are not the rule, conditions exist which promote a greater excretion of calcium than in experimental subjects A so-called minimum calcium requirement does not allow for any storage of that mineral

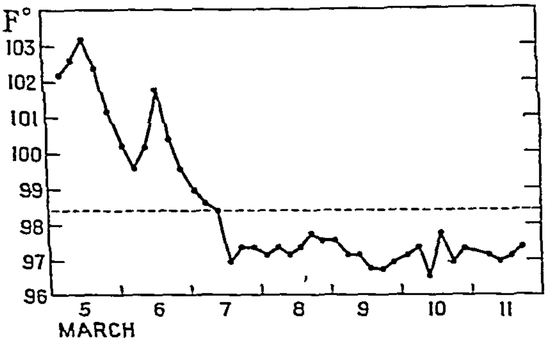
TREATMENT OF BACILLARY DYSENTERY WITH M & B 693

G J BELL, M B Lond , D P M
DEPUTY MEDICAL SUPERINTENDENT OF COLDEAST COLONY
(TATCHBURY MOUNT), SOUTHAMPTON

AN epidemic of dysentery occurred recently at this colony which houses mental defectives of all grades The number of patients affected was 16 Bacteriological investigations carried out by Dr J T Duncan revealed that in this one epidemic there were two types of dysenteric infection *Bacillus dysenteriæ* Flexner W being isolated from the stools of about two-thirds of the cases, and *B dysenteriæ* Sonne from the others In the patients infected with *B dysenteriæ* Flexner the symptoms tended to be much more severe , they exhibited pyrexia up to 104° F , frequent passage of stools consisting of blood and mucus or pure blood, and severe tenesmus The Sonne group only had severe diarrhœa with much mucus and only an occasional trace of blood



The opportunity was taken of treating the condition with M & B 693 This was given in doses of 0 5 g four-hourly by mouth and the average total amount received by each patient was 5 g On this dosage and method of administration no symptoms of intolerance such as nausea or vomiting were shown by any of the patients The results obtained were very satisfactory In all cases treated the symptoms cleared up in 36–72 hours The effect on the pyrexia was immediate and temperatures returned to normal within 24–48 hours After the passing of blood and mucus had ceased there was a period of constipation varying from 2 to 4 days before normal stools appeared In the treated cases there was little variation in the clinical picture The following is an example

An epileptic imbecile aged 27 First symptoms of illness March 5, 1941 Passed frequent loose motions containing blood and mucus Rise of temperature to 103 2° F (see chart) Pulse rate 72–100 Respirations 18–20 Complained of tenesmus M & B 693 one tablet 4-hourly given On the 6th passed only one loose motion containing blood and mucus No complaint of tenesmus Highest temp 101 8° F On the 7th much improved Had one loose motion containing mucus only Highest temp 99° F On the 8th no further symptoms Received 10 g M & B 693 altogether *B dysenteriæ* Flexner W present in stools

The first 2 cases in this series did not receive treatment by M & B 693, and though they were obviously inadequate in number for purposes of comparison the course of the disease in them did differ greatly from that in the treated cases One made a good recovery after exhibiting typical dysenteric symptoms for nearly two weeks The other (a low-grade epileptic imbecile) died after an illness lasting five days

Of the 14 patients who received chemotherapy specimens of bowel material were taken for examination before treatment was begun from the first 8 All gave positive results 5 being found to be infected with *B dysenteriæ* Flexner and the remainder with *B dysenteriæ* Sonne In the subsequent 6 cases treatment was instituted immediately symptoms appeared Specimens for examination were taken at varying periods afterwards, but only in one instance when this was done within 24 hours was a positive result obtained *B dysenteriæ* Flexner being found All patients in this group exhibited typical dysenteric symptoms similar to those shown by the earlier cases

Dysentery bacilli were never found in any specimens taken for examination later than 36 hours after the beginning of treatment with M & B 693 Repeated examinations on all cases treated have so far been entirely negative The specimens for examination were taken by means of rectal swabs In 2 patients there was a recurrence of symptoms of mild degree 5 days and 14 days respectively after the cessation of symptoms but it could not be confirmed bacteriologically that these were either relapses or reinfections They were treated as before with disappearance of symptoms within 24 hours

CONCLUSIONS

Excellent clinical results were obtained by treating Flexner and Sonne bacillary dysentery with M & B 693 The results in the main agree with those obtained by Reitler and Marberg[1] at the Government Isolation Hospital Haifa

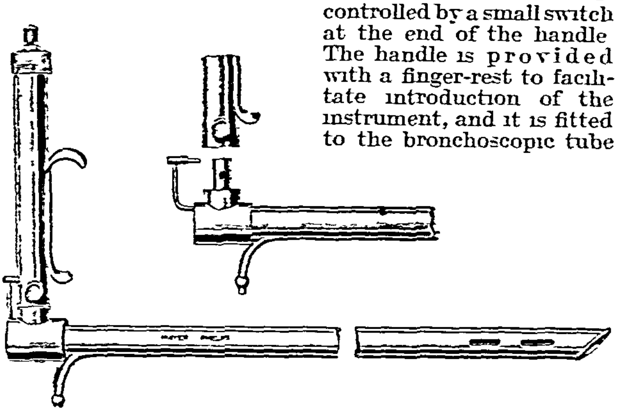
Repeated bacteriological examinations on bowel material from all patients treated have been negative for the presence of dysentery bacilli Further investigations will be made periodically, and if the negative findings are maintained it is evident that the likelihood of patients infected becoming carriers is much reduced by this method of treatment

I am indebted to Dr J T Duncan director of the Winchester laboratory of the Emergency Public Health Laboratory Service, who carried out all the bacteriological investigations and to Dr C J Thomas, principal medical adviser of the Hampshire Joint Mental Health Institutions Committee for permission to publish this article

New Inventions

AN EMERGENCY BRONCHOSCOPE

THE bronchoscope illustrated was designed for bronchial aspiration and insufflation of oxygen in cases of emergency when the facilities of a bronchoscopic clinic are not available The battery for lighting is a dry cell (2 8 v) contained in the handle and the current is controlled by a small switch at the end of the handle The handle is provided with a finger-rest to facilitate introduction of the instrument, and it is fitted to the bronchoscopic tube by means of a screw so that it can readily be removed for sterilisation The bronchoscopic tube is sterilised by boiling and the handle and light carrier by alcohol The built-in tube is used for the insufflation of oxygen and it can be connected to a cylinder by rubber tubing and the gas allowed to flow at the rate of 1 litre a minute The model illustrated is 40 cm long and 10 mm in diameter but the tube can be made in varying lengths and calibre as desired The apparatus is not meant to replace the accepted patterns used in routine practice



The bronchoscope has been made for me by Messrs Mayer and Phelps Ltd

INGROWING TOENAIL

H C WARDLEWORTH NUTTALL
FRCS, FRCSE, DPH
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY

The ætiology of ingrowing toenail has often been misunderstood in the published accounts, and its various effects have been emphasised rather than the essential cause *Even the title is a misnomer, for there is no* ingrowth of the nail The essential ætiology is summed up in two words tight shoes If tight shoes are worn for long a linear ulcer develops from lateral pressure along one or both sides of the nail, usually of the big toe (fig 1A, B and C) Dirt and excessive sweating lead to infection, and overgrowth and swelling of the nail fold follow from venous stasis and œdema (exuberant granulations), this is often accompanied by a fœtid discharge and much pain and disablement Temporary relief may be gained by cutting away the edge of the nail but the symptoms promptly return as the nail grows again Up to a certain stage the condition *may be cured by palliative measures and by wearing* properly fitting shoes, but in many cases these measures fail, largely because the patient persists in wearing tight shoes The following operation gives a radical cure with a minimum of mutilation, and the results allow the patient to go on wearing the shoes which, it seems, are irrevocably decreed by fashion

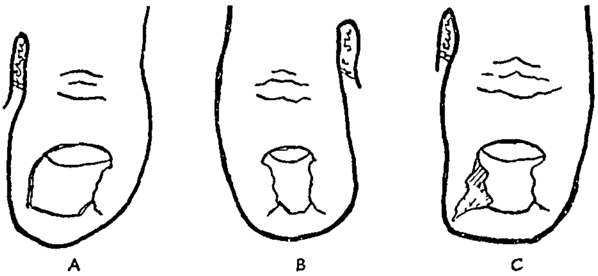

FIG 1—Ingrowing toenail (A) unilateral, (B) bilateral, (C) bilateral with extension

OPERATION

The most convenient position for the foot is flat on the table, and the operator stands at the end of the table The skin of the forepart of the foot having been painted with iodine, local anæsthesia with 1% Procaine is obtained by subcuticular and deep subperiosteal injections over the area indicated in fig 2 When the lateral injections have produced some degree of nerve block the needle is passed gradually under the nail, infiltrating its bed The toe is next fixed by means of a tissue-forceps held by the assistant (fig 3A) It is never wise to allow the toe to be fixed by hand, because however much care is taken the knife is apt to slip and even an expert surgeon may find himself operating on his assistant Incisions follow the dotted lines in fig 3A, clearing any gran tion tissue or lateral extension of it The flap mus dissected up almost as far as the joint line, and incision along the sides of the nail and around the should be carried well down beyond the limits of *nail, and even beyond the tip of the phalanx* The small digital arteries at the sides of the flap are secured by torsion, ligatures tend to pull off The flaps being drawn aside (fig 3B), the nail is dissected from its bed from the free edge upwards, particular care being taken to excise the whole of the matrix at the upper end Unless this is done completely tiny pieces of nail may grow again at the upper angles later, they cause no trouble but spoil the cosmetic effect If the flaps have been properly undercut it will be found that the raw area can nearly always be completely covered, even if it cannot the small area left rapidly skins over The sutures should be of thick silkworm inserted some distance from the margins of the flaps drawn tight with care, otherwise they will cut thro Four usually suffice (fig 3C) A simple dressing of a p of Vaseline gauze the size of a postage stamp, cov with dry gauze and wool, completes the operation patient is allowed to go home and returns a week later the removal of the sutures By this time he or sh usually walking fairly well and within two weeks of operation is back at work Occasionally healing delayed for two or three weeks owing to the gr infection present Drainage is free however, and end-result is as good in these cases as in those wh heal at once

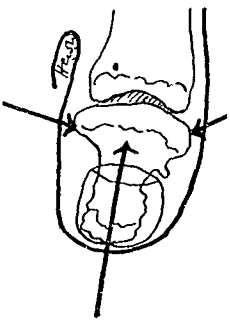

FIG 2—Sites for injectio anæsthetic (arrows)

The operation is radical yet does not shorten the at all, and sensitive patients who wish to wear be shoes are still able to appear with a full complement painted nails by depicting one on the skin The s operation can be used for cases of onychogryphosis avoids the risk of infection of the bone which is alw present when amputation is performed through the di phalanx—a risk which has induced some writers advocate removal of the distal phalanx altoget Although a minor operation its technique is tricky, it is more difficult to perform than amputation disarticulation

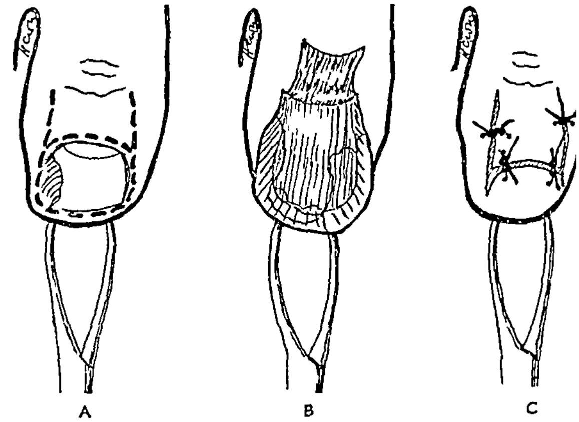

FIG 3—Operation (A) Incisions (B) Elevation of flaps a excision of nail (C) Flaps sutured

LONDON SATURDAY, JULY 26, 1941

MENTAL FITNESS OF U S RECRUITS

A RECENT advertisement called for men and women ined in occupational, vocational or educational chology to enlist in the British Army for the work selecting personnel This betokens a somewhat dy recognition of the assistance to be obtained m psychologists, and of the fact that the soldier's ntal qualities are at least as important as his ysical in estimating his efficiency, or placing him the job where he will be most useful Examination mental fitness has hitherto had far less attention an the physical examination of recruits , it is more fficult to perform, more difficult to assess, more fficult to check, and therefore much more difficult trust The doubts and delays which have here mpered its reasonable application, except in special stances, are now showing themselves in the United ates, where our tribulations of 1939 are being peated There the psychiatric problem has been lly recognised, and excellent instructions have been rculated for the guidance of physicians examining ecruits[1] , but art is long (especially the psychiatric rt) and time is fleeting, and 50 men a day have to e put through each neuropsychiatrist's sieve An formative account of how this is being done comes rom the Boston area[2]

The physicians concerned have a lively sense of hat the problem meant to the United States last me 2% of the men admitted to the army in 917–18 were found to be suffering from neuro-sychiatric disabilities, hardly any of which were due o war service and most of which had begun at least ive years before , a third of these men had some egree of mental deficiency, a sixth were neurotic, and nother sixth were classified as drug addicts, alcoholics r "constitutional psychopathic inferiority" , and y 1927 almost half of all the cases receiving treatment or disorders attributable to war service were neuro-sychiatric cases Each such case has cost approximtely 30,000 dollars to date Nobody wants to incur uch avoidable burdens this time, but there are more eople to be examined under "Selective Service" han could be given the thorough psychiatric overhaul hat might be desired A compromise has been rrived at Men are examined in the first instance y general practitioners (the local board) , dubious ases can be referred to the specialists of the medical dvisory boards (of which there is one to each ten cal boards) , all men approved as A1 at this stage re called up and examined by the medical induction oards, which are the final barrier before actual ntrance into the army On this board there are a edical director from the A M C , and (in the Boston rea, which is presumably typical) five civilian neuro-sychiatrists and a psychologist (non-medical), the ther civilian specialists being a clinical pathologist, n oral surgeon, an otolaryngologist, an ophthalmo-gist, an orthopædic surgeon, a general surgeon and three physicians The allowance of neuropsychiatrists is therefore generous but not excessive The number of men examined daily by the induction board has varied from 100 to 250 In a given month (February, 1941) a third of all rejections were on neuropsychiatric grounds, and they amounted to 5% of all candidates examined by the induction board If the medical director had not refused to sanction some of the neuropsychiatrists' recommendations for rejection, the number of candidates rejected on these grounds would have been more than half as high again The examination by the neuropsychiatrist took from five to ten minutes, the length of time spent on each case being restricted by the number of available psychiatrists and by the necessity to deliver the candidates to the reception centre on the day of induction In justifying this expenditure of time to those who say it is too little, as well as those who say it is too much, four general principles are stated

(1) Individual interests must for the time being yield to the collective interests of the nation

(2) The army needs men sound in mind and body, it is not to be considered a corrective institution for psychopaths

(3) There are 17 million eligible men from whom to choose an army of 2–4 million

(4) The admission of undesirable candidates to the army not only decreases its efficiency but increases the burden on the nation through supporting these men by the army or by the veterans (pensions) bureau

The first of these propositions will command universal assent , the second is flouted by those misguided patriots among examining doctors who can't see why "a bad hat should get away with it" , the third can arouse in our breasts only envy As for pensions, the Americans have prudently set up a dam by providing[3] for further examination and rejection of recruits, if necessary, without providing governmental care or treatment for neuropsychiatric disabilities incurred before entrance into the army or within the first six months after entrance On this score the difficulty is not to make a sensible enactment but to prevent its being set aside by clamour or political pressure

It is instructive to read the proportions of men rejected for the U S Army on neuropsychiatric grounds by the induction board after the local board (which apparently too seldom invokes the aid of its advisory neuropsychiatrist) had passed them A1 The local board's neuropsychiatric rejections numbered 209 out of 4405 candidates 16% of rejections were for mental deficiency, 5% for insanity, 54% for neuroses (including effort syndrome) and abnormal or psychopathic personality, 7% for drug addiction, stammering or enuresis, 4% for epilepsy, and the remaining 14% for neurological disorders But the medical director on the induction board often (159 times out of 245 in the Boston area during February) quashed the neuropsychiatrist's rejection He did this most often where mental deficiency constitutional psychopathic inferiority, schizoid personality, psychoneuroses, post-traumatic syndromes and epilepsy were the diagnoses, and of 11 men recommended for rejection on account of effort syndrome he reversed the decision in every case It seems that the army doctor was less particular than the civilian Light is cast on this by the official plan for "prehabilitation"

Medical Societies

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE

AT the annual general meeting of this society on July 17, with Sir RICKARD CHRISTOPHERS, F R S , the president, in the chair, a paper on the present position of

Yellow Fever in Africa

was read by Dr G M FINDLAY Recent events, he said, had clearly demonstrated the specificity of the mouse-protection test for immunity to yellow fever in the blood of human beings, and had shown that the area which had been marked out by this test as the endemic zone in Africa did coincide closely with the actual distribution of yellow-fever cases The endemic zone now extended from the west coast of Africa just to the north of Cape Verde, along the southern border of the Sahara to the Anglo-Egyptian Sudan , thence bending southwards it crossed the White Nile and extended as far east as, and quite possibly beyond, the Sudan-Abyssinian border , the eastern border of the area extended southwards through the western part of Uganda, thence diagonally across the Belgian Congo to the mouth of the Congo River Any area in this zone was liable to be the site of an explosive outbreak of yellow fever Three epidemiological types of yellow fever could be recognised in Africa—urban epidemicity, rural epidemicity and rural endemicity The first type was carried on by *Aedes ægypti* and was apparently due to the importation of yellow fever from the country into the town in the second type it was impossible to exclude *A ægypti* as a vector since this mosquito was so widely distributed throughout rural Africa The factors favouring rural endemicity were as yet unknown , it seemed unlikely that infection could be maintained solely by the man-mosquito cycle Although 20% of wild monkeys in the endemic zone were known to contain immune bodies in their blood it was not considered likely that monkeys were sufficiently numerous to carry on infection in the absence of man The possibility of other alternative hosts must therefore be considered So far no wild animals other than one ostrich had been found to possess immune bodies in their blood, although in Colombia marsupials and certain other wild animals had been found to possess an acquired immunity The sera of numerous domestic animals in Africa—cows, sheep and goats, horses, pigs, dogs and a camel—had been found to contain virucidal bodies against yellow fever The specificity of the mouse-protection test as applied to animals required further investigation, but the results so far obtained were suggestive The possibility of a reservoir other than the mosquito but with a longer life could not be altogether excluded The two chief problems in relation to yellow fever in Africa were the more efficient control of yellow fever in the endemic zone and the prevention of the spread to East and South Africa with further extension to India and the Far East Infection could be carried either by the infected mosquito or by the infected human host Owing to the greater rapidity and the greater volume of traffic there was now much more chance of the virus spreading from the present endemic area and being carried either by plane, motor-car, ship or train to non-endemic areas If infection reached East Africa there was at present a considerable chance of it passing across to Southern Arabia and India, since the dhow traffic was a replica of the shipping which during the 17th and 18th centuries carried yellow fever between Africa and America

The methods of preventing the extension of yellow fever comprised more concentrated attacks on the breeding of mosquitoes, more efficient control of aerodromes and of people travelling by car from endemic to non-endemic zones In immunisation was to be found a most efficient means of prevention, and it was time that regulations were promulgated to forbid the residence in any yellow-fever area of all non-Africans who had not been immunised against the disease In certain selected areas mass immunisation of the whole population must be considered At present the greatest difficulty in the efficient control of yellow fever lay in the multiplicity of authorities, each of whom was concerned solely with the condition of affairs within its own borders Until there was greater correlation of administrative effort yellow fever would continue to be a menace to the health of Africa and of the whole tropical world

Dr HUGH SMITH (International Health Division of the Rockefeller Foundation), who had recently been in charge of yellow-fever investigations in Colombia, gave a brief account of the present position in South America In the past three years there had been no instance of an outbreak transmitted by *A ægypti*, although there had been many outbreaks of jungle yellow fever In Colombia yellow fever recurred again and again at intervals of one or more years in the same isolated valleys, often within a short distance of a previous outbreak Intensive studies had been made of all outbreaks and so far no other arthropod other than mosquitoes had been found infected On eight occasions, however, virus had been isolated from wild hæmagogus mosquitoes It was very difficult to account for the continuance of yellow fever in these areas, some of which were almost uninhabited A high percentage of monkeys' bloods were positive for yellow fever thus strongly supporting the suggestion that yellow fever could maintain itself in the absence of man Although yellow-fever virus did not pass from one generation of *A ægypti* to another through the egg it was possible that this might happen with other mosquito vectors and this question was now being investigated The absolute impossibility of diagnosing yellow fever on clinical grounds was stressed In eradicating yellow fever it was essential to combine immunisation with eradication of *A ægypti*, but it was not always easy to immunise a high proportion of the population Efforts were now to be undertaken to eradicate *A ægypti* from the whole of the Amazon Valley

Colonel F P MACKIE drew attention to the difficulties imposed on air travellers by the differing regulations in force in different countries Some countries accepted a certificate of non-exposure for 6 days , others insisted that if a person had been immunised against yellow fever he could not be admitted for 10 days , others extended the period to 21 or 23 days —Colonel THOMAS MENZIES asked if combined vaccination against smallpox and yellow fever was recommended It had been practised in certain French colonies —Dr H S STANNUS said he had never seen a case of blackwater in an African, although such cases had been recorded He suggested that they might in reality have been cases of yellow fever —Prof T F HEWER drew attention to the difficulty in diagnosing cases of acute and subacute liver necrosis from yellow fever Such cases, which were not uncommon, might in Africa be associated with black vomit

Dr FINDLAY, in reply, said that it was now generally agreed that people who had been inoculated against yellow fever were immune to the bite of an infected mosquito 10 days later There was no scientific justification for imposing quarantine periods of 21 days or over —Dr HUGH SMITH concurred It was impossible for anyone who had lived in an endemic zone to say that they had not been exposed to yellow fever and therefore certificates of " non-exposure " granted by any country in the endemic zone were farcical So long as immune bodies could be shown to be present in the blood by the mouse-protection test there was no need for reimmunisation If it was impossible to have a mouse-protection test carried out it was advisable to be reinoculated every two years, although there was considerable evidence to show that anyone who had ever had immune bodies in his blood was immune for a considerable number of years Combined inoculation by scarification of vaccinia and yellow fever was not favoured Dengue and yellow fever gave no cross immunity

---

INDEX TO THE LANCET, VOL I, 1941

The Index and title-page to Vol I, 1941, which was completed with the issue of June 28, will be ready shortly A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now principle, long used in bacteriology, is to freeze the plasma, and then, in a high vacuum, to distil off the water vapour into a condenser cooled to a much lower emperature with, say, solid CO_2 This has the dvantage of producing a really dry plasma—perhaps ess than 0 1% residual water—in the form of a light powder Several special methods have been devised on this basis **Flosdorf** and **Mudd**'s "lyophile" pro-ess[4] used solid CO_2 dissolved in methyl cellosolve as the cooling agent, their "cryochem" process[5] enabled arger quantities to be dealt with more efficiently by utilising a chemical absorber of water vapour (calcium ulphate) Both methods suffered from the disad-vantage of being discontinuous, every so often the process had to be stopped to get rid of the condensed water, and then the apparatus had to be re-sterilised and the temperature gradient regenerated To over-come this **Flosdorf** and **Mudd**[6] introduced their "desivac" process, using a specially designed oil-pump, with this up to 100 litres can be dried at a time One of the major difficulties of large-scale drying is the maintenance of sterility, and if the dried product is obtained in bulk contamination is liable to occur while it is being transferred from the apparatus to the storage containers In the small-scale apparatus the drying is actually carried out in the final container which is sealed off when drying is complete **Folsom**[7] makes use of a series of units each drying 250–500 c cm of plasma by a lyophile technique, he claims that it is efficient and relatively inexpensive to set up, a ten-unit set costing about £60, but the special containers needed can only be used once **Greaves** and **Adair**[8] overcame this objection by having a large drying chamber in which stacks of plugged sterile tubes of plasma or serum could be placed and drying actually took place in the plugged tubes The principle of their apparatus was also high-vacuum condensation drying but they used a methyl-chloride refrigeration plant for the necessary cooling and combined it with a highly efficient system of temperature control to obtain the optimum condi-ions This type of apparatus is relatively expensive o instal but once set up is claimed to be almost automatic As much as 5 litres of serum could be dried at a time and modifications of this plant are said o be able to handle even larger quantities Serum ried by this method has been found[9] on reconstitu-ion to maintain its normal physicochemical proper-ies, especially osmotic pressure, but it gives an palescent solution thought to be due to some change, not apparently harmful, in the serum lipids **Brown** and **Mollison**[10] have reported satisfactory clinical results with serum dried in the Greaves-Adair apparatus, but they noted that 5 minutes' vigorous shaking with water at 40° C was necessary to get the powder to dissolve at normal strength, and for concentrated solutions it was best to prepare the solution overnight

The ideal has clearly not yet been reached, and yet another principle is being inquired into This is "spray drying," as used on an industrial scale for the preparation of dried milk Here warm air is used to blow the liquid through fine jets into a chamber, the water evaporates rapidly from the fine particles and is carried away on the air-stream, the dried powder falling to the bottom This produces a fine easily soluble powder of the type required It was probably not applied to plasma drying because of the relatively large-scale experiments needed and the difficulties of effective sterilisation, but research is proceeding along these lines in at least one centre and there is evidence that the difficulties can be overcome

When the method has been chosen, is plasma or serum to be dried? Plasma has so far held the field because it is a by-product of the blood-banks and because of adverse clinical reports on the use of serum The drying plants described will deal with the products of 100–500 pints of blood at a time, and in fact must be fed with these large amounts to work economically and efficiently It is clear that only the large blood-banks can provide such quantities and that the blood will be specially drawn for producing serum or plasma In this case it is far simpler to produce serum from the start—it is easier to prepare, many filtration difficulties are eliminated, and thorough drying is easier in the absence of citrate Satisfactory clinical reports of the use of serum have come from this country[10] and America,[11] and the Canadian Government have chosen serum to send to this country and for their army medical services **DeGowin** has rightly said that "the object of any service supplying blood and blood products should be to make them available as far forward as possible" It is safest in the present war to assume that the forward zone may be anywhere in the world A properly dried serum can be sent anywhere with the minimum of trouble and stores can be accumulated for emergencies without special expensive storage plant It is to be hoped that agreement will soon be reached on the best method to be employed and that adequate quantities of dried serum will then be available for use anywhere

Course in Industrial Medicine at Sheffield—The first of a series of postgraduate courses in industrial medicine arranged by the faculty of medicine of Sheffield University was held on July 4–6, at the Royal Hospital and Royal Infirmary Forty doctors were present when Dr J C Bridge, senior medical inspector of factories, gave the opening lecture on the medical aspects of factory legislation Dr C L Sutherland, chief medical officer of the Silicosis and Asbestosis Medical Board, showed X-ray films of silicosis, asbestosis and byssinosis, and Dr Henry Blyth another officer of the board, silicotic lungs, Dr A I G McLaughlin, a medical inspector of factories, demonstrated the effects of the inhalation of non siliceous dusts in industry, Mr H N Boddy, Ph D (Safety in Mines Research Board) showed quartz dust and silica particles in dried lung tissue, Miss May Smith, D Sc (Industrial Health Research Board) lectured on fatigue, boredom and monotony in factory life, Dr Rupert Hallam discussed occupational dermatitis, Mr E W Murray, director of the Home Office Industrial Museum, lectured on ventilation and heating in factories, Dr J L Grout demonstrated the X-ray appearances of the wrist bones of pneumatic tool-workers, and Dr John Wilkie typical bone changes in fluorine osteosclerosis, and Mr A B Nutt, showed apparatus used in industry to protect the eyes During a visit to Messrs Edgar Allen and Co the class was shown the process of welding and the details of the manufacture of steel castings, and the practical measures adopted to prevent the inhalation of silica dust given off during the fettling of the castings

of registrants, in which concern is shown about the high proportion of rejects

> "To date the number of deferments and rejections has been large, so great indeed that considerable concern is evident in Selective Service, in the Army, and in the country as a whole It is estimated that less than 20% of the 16,500,000 registrants are being classed available for general military service Selective Service local boards at the present time are classing 20% of those physically examined in class IV-F, as being totally disqualified for military service, 12% in class I-B, as being fit for limited military service only, and 68% in class I-A, as being qualified for general military service Of the 68% classed as being qualified for general military service and sent to the Army Induction Station, about 12% are being rejected because of physical, mental, moral, administrative and other reasons Criticism has been abundant and bitter and is on the increase "[4]

A plan is therefore put forward to make men aware of the physical standards required by the army, and to encourage them to seek medical advice in advance in order to make themselves fit to serve Such men will then bring to the examining board a certificate of "prehabilitation" the obtaining of which "will tend to indicate character and the possession of desirable qualities—intelligence, forethought, initiative, fitness and a desire to serve—all of which must go into the making of a good soldier It should serve to diminish the number of rejections, with all the attendant humiliation and inconvenience involved" Evidently too high a standard of fitness for army service may have unwelcome effects on the civilian population But it has to be remembered that many unsuitable men cannot be detected as such until they are in the training camp

There is agreement among the American neuropsychiatrists who have lately written on the subject,[5] in the light of their experience on induction boards, that a great deal can be done by an experienced neuropsychiatrist in five to ten minutes of well-conducted interviewing, and that another ten minutes would not give much more that is practical and necessary for a decision The testing of intelligence may be an essential part of the procedure It could not be carried out by the physician limited to ten minutes for his whole examination, but must be regarded as an additional investigation The Boston induction board has had the advice of a group of Harvard psychologists[6] Group tests were looked on as impracticable "for both administrative and technical reasons" These objections are well known here, but it is surprising that they were regarded as decisive against the method The tests used by the Boston psychologists were, however, less suitable to group testing on the whole than the progressive matrices test of RAVEN which has been much employed in this country The subjects were referred by the psychiatrist as suspect of being below the mental age of 12 years (the critical level of capacity set by the U S Army recently, but questioned by the writers as too high) though it is well recognised that the basic question is not mental age but "is this man equal to the demands that will be made on him by the army?" Very brief examination by the psychologist disposed of the few candidates who were below the 10-year or above the 14-year level, those in between required more attention Self-administered tests,
with printed instructions (comparable to those whi
have also been widely used in the Army here), w
found unsatisfactory in Boston because many of t
subjects were unaccustomed to reading and w
therefore handicapped in grasping what they had to
The examiners say that they felt keenly the lack
non-verbal material that would be adequate and n
time-consuming, probably our experience with n
verbal tests could be of use in this connexion T
Boston psychologists advise flexibility in the use
individual tests "It is important," they say, "
have clinicians who are qualified to use their o
judgment concerning the techniques that will ena
them to give a reasonably accurate approximati
of intellectual levels" Out of 5100 men pass
through the induction station during 16 days, 1
were referred by the neuropsychiatrist for psych
metric examination, 79 of these were given a rat
of less than 12 years, 120 a rating of 12 or over T
regular psychological examination of recruits
deferred until they arrive at the reception stati
where a fairly elaborate series of tests is applied

DRIED PLASMA AND SERUM

The Ministry of Health's regional blood-transfus
services are now producing significant quantities
blood, plasma and serum, and are planned on a sca
to provide these materials in excess of local needs
some of the regions have a surplus already Accordin
to *Science* of June 13, our American colleagues think
in terms of a hundred million quarts What is to be
done with these large volumes, little of which will b
required for use immediately after collection? In thi
country it is likely that liquid plasma or serum wil
always be preferred since it is available for instant use
but for overseas or for reserve stores intended to kee
more than a few months dried plasma or serum has grea
advantages, it is stable, transport weight and spac
are relatively small, and, so long as there is a prope
supply of pyrogen-free distilled water at the receivin
end, it can be readily reconstituted by simple solutio
in distilled water Numerous methods for preparing
dried plasma have been described, they all aim
at distilling off the water without denaturing
the proteins and in such a way that the produc
is easily soluble, sterility must be maintaine
throughout

The most obvious method is simple in-vacuo distilla
tion, allowing the water to be boiled off at a tempera
ture well below 37° C There is usually an arrange
ment which allows the liquid plasma to be run into
the distillation chamber in a continuous stream o
spray without stopping the process An efficien
system of this type was described by AYLWARD,
MAINWARING and WILKINSON,[1] but although the
product was satisfactory they found the method
unsuitable for large-scale production HARPER
ESSEX and OSTERBERG[2] used an essentially similar
technique which they incorrectly call "spray distilla
tion", their account[3] of clinical experience with
their dried product brings out one of the disadvantage
—the residual water content may be as high as 8%,
which diminishes its keeping qualities A second

may regress and disappear, and that symptoms tend to undergo spontaneous remission. Certain general conclusions may nevertheless be drawn. Operative excision of a deposit will always promptly relieve the acute bursitis to which it has given rise, and symptoms do not tend to recur; operation may be performed under local anæsthesia, requires only a few days' hospitalisation, and should be followed by return to work with full movement in 3 weeks. Irrigation, while it relieves an acute bursitis and clears the bursa of suspended calcareous debris, does not necessarily affect the initial tendinous focus which may recur, nor should it be undertaken in outpatients. Diathermy and short-wave therapy are only to be regarded as ancillary and postoperative forms of treatment, and immobilisation alone is pernicious because of adhesion formation. If special surveys of this type become popular the management of the case with radiographic findings but no symptoms will assume some importance. Bosworth advocates routine excision of large deposits, since they inevitably cause trouble at some time; the smaller ones should be observed occasionally. What is clear is that calcification in the tendinous cuff of the shoulder-joint capsule is a continuous and often self-limiting process for which it can no longer be asserted that operation is necessary on the results of a single observation.

A LONG SYMBIOSIS

The Reading Pathological Society met for the first time on July 13, 1841, at the then two-year-old Royal Berkshire Hospital, and today the two centenarians are still cronies. The society has always met at the hospital, and the hospital at once gave it free use of the library on condition that all the books "whether already purchased or added in the future" should be the property of the hospital. The enterprising and lively society soon realised how important a library was for the distribution of knowledge, especially perhaps to those working in the comparative isolation of country practice, and by 1883, when a new library was opened in the west wing of the hospital a valuable reference collection had been amassed largely through the society's efforts. At the commemorative meeting of the society on July 17, in recognition of this, the Rev. Harvey Thursby, chairman of the hospital board, formally presented the books to Dr. George Halpin, president of the society, as a centenary gift. Dr. G. O. Lambert, who gave the centenary oration, chose as his subject "The Reading Pathological Society—One Hundred Years in Retrospect" and illustrated his address with pictures of past members, the society's crest, and the president's badge, an effigy of Imhotep designed by the late Dr. Jamieson Hurry. Speaking of the function of medical societies, Raymond Crawfurd once said that men's minds are massaged by rubbing against each other. The Reading Pathological Society has a record of a hundred years of such beneficial friction behind it and we have every confidence that it will continue to rub along.

GLYCOGEN DISEASE OF THE LIVER

Some confusion still exists over the biochemical and clinical findings in glycogen disease of the liver, partly owing to conflicting data in the numerous cases reported, and partly to a failure to differentiate clearly between the various diseases which may give rise to excessive glycogen storage in the liver. Ellis and Payne[1] consider the following biochemical findings to be typical: a low fasting blood-sugar which fails to rise after the injection of adrenaline; a delayed fall in blood-sugar after the ingestion of glucose; and a rise in blood-sugar which sometimes occurs in the half hour after the ingestion of lævulose. The glycogen and cholesterol of the blood are raised and acetonuria is found. Mason and Andersen[2] tried to classify the reported cases under two divisions—cases in which the main deposit of glycogen is in the liver, and those in which it is mainly in muscle, including that of the heart. They have singled out subgroups under these headings according to the degree of hepatomegaly and the presence or absence of fructosuria or galactosuria, cases of abnormal insulin regulation including diabetes mellitus, and cases in which there is an apparent inability to transform glycogen to dextrose in the liver. They suggest that glycogen storage disease of the liver should include the cases in which the chief deposit of glycogen is in the liver, and that "von Gierke's disease" should be employed only for cases where excess deposit of glycogen in the liver results from inability of the liver to break down glycogen. The cause of excessive storage of glycogen has excited considerable controversy. Von Gierke himself considered that the liver glycogen was persistent fœtal glycogen which is comparatively stable. Endocrine theories incriminating the adrenals, pituitary or pancreas have been put forward. Hyperinsulinism certainly would account for the low fasting blood-sugar or the occasional attacks of hypoglycæmia, but it does not explain the acetonuria. Ellis and Payne and others have said that the high dextrose-tolerance tests suggest an abnormally slow rate in the storage of sugar as glycogen, and that the enzyme responsible for glycogen storage and breakdown is reversible. In these circumstances it would be difficult to explain how the glycogen was originally stored in the liver in such large quantities. Mason and Andersen have reported enzyme and chemical studies in an affected child from birth until death at the age of 2 months. They think their case was due to a defect in the reversible enzyme system in the liver, whereby the intermediate stages in the conversion of glycogen to dextroses were interrupted. They point out, moreover, that as carbohydrate metabolism is associated with a complex system of enzymes, the concept of a single enzyme "glycogenase" should be discarded. Their theories and experimental evidence have gone far towards elucidating the cause of the disease and give a more satisfactory explanation of the divergent biochemical findings than any other.

TOXICITY OF SULPHONAMIDES

In man the most common toxic effects of the sulphonamide drugs are on the blood, so that it seems more reasonable to measure their toxicity by their destructive action on the blood of mice than by determining the lethal dose. Richardson[1] has used such a method in testing the toxicity of four of these drugs and has shown a relationship between their chemical structure and hæmolytic activity. For each drug he incorporated graded amounts in the diet of 50–60 mice for 14 days and then studied the changes in their hæmoglobin and reticulocytes, and in the formation of abnormal blood-pigment. He also investigated the relation of the blood concentration of the drugs to intake and the distribution between plasma and erythrocytes. The minimum intakes of the four drugs required to produce hæmolysis expressed in g. per kg. per day, were: sulphanilamide 0·12, sulphapyridine 0·31, sulphathiazole 0·52 and sulphanilylguanidine 1·3, so that, for the same dosage, sulphanilamide was twice as injurious to the blood as sulphapyridine, four times as injurious as sulphathiazole and nearly eleven times as injurious as sulphanilyl-guanidine, which is poorly absorbed from the gut. There were striking differences in the distribution of the drug between plasma and cells. With sulphanilamide and sulphanilyl guanidine most of the drug was in the cells, with sulphapyridine the distribution was more nearly equal, whereas with sulphathiazole the greater part was in the plasma. It was found that the minimum concentrations in the erythrocytes required to produce hæmolysis were,

PERIODIC DULLNESS

Anyone who has lived with epileptics must realise that many of them suffer from periods of dullness, the characteristics of which are unusually slow response, failure of memory, especially for recent events, and a mild degree of confusion Not uncommonly there is a change of emotional tone The patient may be more irritable or more apathetic than usual But the main change is often in the intellectual, rather than the emotional sphere, and the school-teacher or the nurse reports that the patient "seems half dazed" Careful observation shows that in many cases these periods are self-limited, lasting perhaps for hours perhaps for some days They are not part of a general mental deterioration, they bear no relation to sedative drugs, and they are not pre- or post-fit phenomena How are we to explain them ? The most obvious thing is to class them as epileptic equivalents or variants and leave it at that In some cases one is led to suspect that the patient is suffering from repeated very slight attacks of petit mal, with constant interference with the stream of consciousness, and this can sometimes be demonstrated by getting him to read out loud when the little breaks in consciousness become obvious Short of these there may be serial attacks so slight as not to be clinically demonstrable Whatever their explanation, these dull periods are a very serious manifestation of the complaint Putnam and Merritt[1] give details of 10 cases in which periodic dullness was a prominent symptom They are able to correlate it with abnormal electric rhythm in the cortex, the abnormality usually consisting of slow square topped waves of the type associated with psychomotor attacks rather than with the wave and spike formation of petit mal attacks or absences They further show that it can be removed clinically and on the electroencephalogram by treatment with sodium diphenylhydantoinate (Epanutin) The evidence for the periodicity and self-limitation of the dullness in some of the cases they cite seems incomplete, and its disappearance at the same time as the removal of major and other attacks by drug treatment suggests that the dullness might be a direct outcome of the attacks Nevertheless, their clinical results are sufficiently encouraging to lead them to consider whether periods of dullness and slight mental confusion in subjects not liable to fits might be expressions of similar alterations in cortical rhythm and could be removed by similar means

CERTIFICATION OF INJURIES IN WAR-TIME

When war broke out local emergency committees had ready for distribution to all medical practitioners a memorandum from the Ministry of Health explaining how to issue certificates for the payment of "injury allowances" Doctors agreed to furnish these certificates without fee and in a memo just issued (Ministry of Health, No 248) revising these instructions the Minister of Pensions thanks them for their generous cooperation Under the Personal Injuries (Emergency Provisions) Act 1939 allowances are paid to those rendered incapable of work in two distinct categories—the allowance to be replaced by a pension where disablement is prolonged

War injury is defined as physical injuries caused by the discharge of any missile (including liquids and gas), the use of any weapon, explosive or other noxious thing, the doing of any other injurious act either by the enemy or in combating the enemy or in repelling an imagined attack by the enemy, or by the impact on any person or property of any enemy or allied aircraft or anything dropped from it

War Service injury is defined as any physical injury to a volunteer arising out of and in the course of the performance of his duties as a member of the civil defence organisation

Thus both war injury and war-service injury mea physical injuries only Injury to the brain or to t eyesight as a direct result of concussion, cases of sho originating from direct exposure to bomb explosion blast in which the incapacity for work starts from t time of the incident, collapse from heart failure as direct result of an air-attack and similar casualties ma be accepted as physical injuries The definition do not cover neurasthenia or similar sickness in which t symptoms are induced merely by apprehension and fea of enemy activity and a certificate should not be issu to these patients, if they are insured they are entitl to health-insurance benefits Insured persons incapab of work because of war or war-service injuries a disentitled to sickness benefit for incapacity arising fro that injury, but after 26 weeks modified sickness disablement benefit may be paid, while people who a injured while incapable of work because of some oth disability do not receive a war or war service inju certificate until the other injury ceases to be the cau of incapacity Injury allowances are administered the area officer of the assistance board, acting as age of the Ministry of Pensions

CALCIFIED DEPOSITS ROUND THE SHOULDER

Last year R L Patterson and P D Wilson[1] discuss the value of irrigation of the subacromial bursa in t treatment of the painful shoulder, while dramatic rel could often be obtained in attacks of acute bursitis the noted that the effects on areas of calcifying tendinit were not equally satisfactory A great part of th difficulty in estimating the results of treatment of calcified lesions in this situation lies in the lack of knowledge of the natural history of these deposits, and for this reason Bosworth[2] has studied the shoulders of 5061 presumably normal employees of the Metropolitan Life Insurance Company of New York over 3 years Radiography was always preceded by careful screening, since only by inspection during full rotation of the humeral head can every deposit be picked up and its fullest extent visualised Some degree of calcification was present in 2 7% of the total and was half as common again in men as in women, the age incidence rose steadily up to 50, when it fell off abruptly Half the cases were bilateral and the right side was affected twice as often as the left in the remainder No relation could be demonstrated between the deposits and focal sepsis, rheumatism or other disease, and the blood-calcium was invariably within normal limit Occupational incidence, however, was striking, in all age-groups typists were affected roughly twice as often as clerks, a finding that supports Codman's[3] views on the rôle of continued abduction in the ætiology of supraspinatus rupture and tendinous calcification Trauma did not seem to be causative, though it occasionally precipitated the onset of an acute bursitis As regards site, the deposits were found in the supraspinatu, infraspinatus and teres minor in that order of frequency and only occasionally in the subscapularis Repeated screening showed that deposits could accumulate gradually and disappear over a period of years without ever giving rise to symptoms In fact, only 70% o the radiographically positive cases developed symptoms during observation, but it was noticed that the larg plaques, 1 5 cm or more in diameter, invariably caused pain or acute bursitis at some stage Symptoms ranged from a mild occasional twinge to a disabling attac of acute bursitis, and the commonest complaint wa of nocturnal discomfort and limitation of abductio The difficulty in assessing the value of a particular li of treatment is associated with the fact that 30% o cases are asymptomatic, that all but the largest depo ay regress and disappear, and that symptoms tend to ndergo spontaneous remission Certain general conusions may nevertheless be drawn Operative excision a deposit will always promptly relieve the acute ursitis to which it has given rise, and symptoms do ot tend to recur, operation may be performed under cal anæsthesia, requires only a few days' hospitalisaon, and should be followed by return to work with full novement in 3 weeks Irrigation, while it relieves an cute bursitis and clears the bursa of suspended calareous debris, does not necessarily affect the initial endinous focus which may recur, nor should it be ndertaken in outpatients Diathermy and short-wave herapy are only to be regarded as ancillary and postperative forms of treatment, and immobilisation alone s pernicious because of adhesion formation If special urveys of this type become popular the management of he case with radiographic findings but no symptoms ill assume some importance Bosworth advocates outine excision of large deposits, since they inevitably ause trouble at some time, the smaller ones should be bserved occasionally What is clear is that calcification n the tendinous cuff of the shoulder-joint capsule is a ontinuous and often self-limiting process for which it can no longer be asserted that operation is necessary on he results of a single observation

A LONG SYMBIOSIS

THE Reading Pathological Society met for the first ime on July 13, 1841, at the then two-year-old Royal Berkshire Hospital, and today the two centenarians are still cronies The society has always met at the hospital, and the hospital at once gave it free use of the library on condition that all the books "whether already purchased or added in the future" should be the property of the hospital The enterprising and lively society soon realised how important a library was for the distribution of knowledge, especially perhaps to those working in the comparative isolation of country practice, and by 1883 when a new library was opened in the west wing of the hospital a valuable reference collection had been amassed argely through the society's efforts At the commemo-ative meeting of the society on July 17, in recognition of this, the Rev Harvey Thursby, chairman of the ospital board, formally presented the books to Dr eorge Halpin, president of the society, as a centenary ift Dr G O Lambert, who gave the centenary ora-ion, chose as his subject "The Reading Pathological ociety—One Hundred Years in Retrospect" and illus-rated his address with pictures of past members, the ociety's crest, and the president's badge, an effigy of mhotep designed by the late Dr Jamieson Hurry peaking of the function of medical societies, Raymond rawfurd once said that men's minds are massaged by ubbing against each other The Reading Pathological ociety has a record of a hundred years of such beneficial ction behind it and we have every confidence that it ill continue to rub along

GLYCOGEN DISEASE OF THE LIVER

SOME confusion still exists over the biochemical and inical findings in glycogen disease of the liver, partly wing to conflicting data in the numerous cases reported, nd partly to a failure to differentiate clearly between e various diseases which may give rise to excessive lycogen storage in the liver Ellis and Payne[1] consider e following biochemical findings to be typical a low sting blood-sugar which fails to rise after the injection adrenaline, a delayed fall in blood-sugar after the gestion of glucose, and a rise in blood-sugar which metimes occurs in the half hour after the ingestion of vulose The glycogen and cholesterol of the blood are ised and acetonuria is found Mason and Andersen[2] tried to classify the reported cases under two divisions—cases in which the main deposit of glycogen is in the liver, and those in which it is mainly in muscle, including that of the heart They have singled out subgroups under these headings according to the degree of hepatomegaly and the presence or absence of fructosuria or galactosuria, cases of abnormal insulin regulation including diabetes mellitus, and cases in which there is an apparent inability to transform glycogen to dextrose in the liver They suggest that glycogen storage disease of the liver should include the cases in which the chief deposit of glycogen is in the liver, and that "von Gierke's disease" should be employed only for cases where excess deposit of glycogen in the liver results from inability of the liver to break down glycogen The cause of excessive storage of glycogen has excited considerable controversy von Gierke himself considered that the liver glycogen was persistent fœtal glycogen which is comparatively stable Endocrine theories incriminating the adrenals, pituitary or pancreas have been put forward Hyperinsulinism certainly would account for the low fasting blood-sugar or the occasional attacks of hypoglycæmia, but it does not explain the acetonuria Ellis and Payne and others have said that the high dextrose-tolerance tests suggest an abnormally slow rate in the storage of sugar as glycogen, and that the enzyme responsible for glycogen storage and breakdown is reversible In these circumstances it would be difficult to explain how the glycogen was originally stored in the liver in such large quantities Mason and Andersen have reported enzyme and chemical studies in an affected child from birth until death at the age of 2 months They think their case was due to a defect in the reversible enzyme system in the liver, whereby the intermediate stages in the conversion of glycogen to dextroses were interrupted They point out, moreover, that as carbohydrate metabolism is associated with a complex system of enzymes, the concept of a single enzyme "glycogenase" should be discarded Their theories and experimental evidence have gone far towards elucidating the cause of the disease and give a more satisfactory explanation of the divergent biochemical findings than any other

TOXICITY OF SULPHONAMIDES

IN man the most common toxic effects of the sulphonamide drugs are on the blood, so that it seems more reasonable to measure their toxicity by their destructive action on the blood of mice than by determining the lethal dose Richardson[1] has used such a method in testing the toxicity of four of these drugs and has shown a relationship between their chemical structure and hæmolytic activity For each drug he incorporated graded amounts in the diet of 50–60 mice for 14 days and then studied the changes in their hæmoglobin and reticulocytes, and in the formation of abnormal blood-pigment He also investigated the relation of the blood concentration of the drugs to intake and the distribution between plasma and erythrocytes The minimum intakes of the four drugs required to produce hæmolysis expressed in g per kg per day, were sulphanilamide 0 12, sulphapyridine 0 31, sulphathiazole 0 52 and sulphanilyl-guanidine 1 3, so that, for the same dosage, sulphanilamide was twice as injurious to the blood as sulphapyridine, four times as injurious as sulphathiazole and nearly eleven times as injurious as sulphanilyl guanidine, which is poorly absorbed from the gut There were striking differences in the distribution of the drug between plasma and cells With sulphanilamide and sulphanilyl-guanidine most of the drug was in the cells, with sulphapyridine the distribution was more nearly equal whereas with sulphathiazole the greater part was in the plasma It was found that the minimum concentrations in the erythrocytes required to produce hæmolysis were,

THE CASE FOR A NATIONAL HOSPITALS BOARD

G STEWART SMITH, M A (Admin), M D Manc

MOST writers on hospital policy seem to agree that ne form of regionalisation is desirable The latest ort in this direction, the Nuffield Provincial Hospitals ist, *which is an attempt to implement and extend the* ommendations of the Sankey Commission, is at sent only at the stage of discussing boundaries and eres of influence, *and it is by no means certain that* will have the necessary prestige and persuasive power break down the barriers which have hitherto pre- ited the full success of every coordinating scheme der the Nuffield scheme the voluntary and municipal spitals, within both the divisions and the regions, are ected to achieve a large measure of coordination and Central Hospitals Council is to be in charge of major s of policy and to be a supreme directing council the outset it has been decided to invite the provincial mbers of the British Hospitals Association to be a leus of this body which will in fact develop into a ovincial Hospitals Board This leaves unsolved two ge questions which are really the crux of the matter

Is there still a need for the two types of hospital to exist by side , if not, is a merger of the two systems desirable practicable ?

2 What is the best type of central controlling body for the spitals ?

A UNIFIED HOSPITAL SYSTEM

The efforts at coordination between the voluntary and unicipal hospitals have had only a small measure of ccess, mainly because of the essential independence of e units in the voluntary system and the absence of any al urge to combine The P E P report says, “ The mplete merging of the two systems, if it comes, will dently not be completed for a very considerable me ”, but public opinion has moved far since 1937 hen this report was published The voluntary hos- tals are coming to depend to an increasing degree on ntributory schemes and are pressing for further help m the rates—that is, they are becoming less dependent voluntary subscriptions and are getting paid for larger proportion of their work Under the Nuffield ust plan the local authorities will no doubt be expected pay for much of the cost of regionalisation both by a levy and increased donations The removal of the gma of pauperism from the local-authority hospitals ich the 1929 act brought about and their consequent reased use by a widening section of the community e helped to narrow the gap between the two systems large centres the differences between the type of per- admitted to the voluntary and municipal hospitals based not on income level but on the type of disease n which the patient is suffering, and these differences not sufficient to justify the maintenance of two tems It is often maintained that medical work, ecially medical research and teaching, flourish best in atmosphere of freedom found in the voluntary hos- ils, but it has yet to be proved that they cannot urish equally well under a unified hospital system

fter the war some increase of hospital accommodation r the pre-war level will be necessary and extensive uilding will have to be carried out The voluntary pitals, *who find difficulty* in keeping up with their sent commitments, can hardly be expected to provide expansion , on the other hand, if the programme is ned out by the *municipal hospitals* they will gradually rtake the voluntary hospitals and become the more ortant of the two systems It may be that the field scheme, which *would encourage* the hospitals to a for the division or region as a whole and is prepared ubsidise within the limits of its small income any ital, voluntary or municipal, which fits into this , will succeed, but to quote the P E P report again, e ultimate control will rest in the hands of those who these services, of those who pay for *them* and of e who provide them ” If the local authorities and a degree of representation proportional to their financial support, as seems likely, the coordinated service will become more and more municipalised In any case a merger cannot result in a completely voluntary service

The Minister of Health will presumably watch the development of the Nuffield scheme and if it succeeds might encourage regional planning by financial support He might do this by making a direct grant for hospital services, by taking hospital provision into consideration when making the block grant, or by defraying a proportion of the cost of any divisional or regional scheme of which he approved This would have the advantage of fostering regionalisation with a small measure of central control through finance while giving much local autonomy and leaving medical practice but little disturbed Any local schemes are bound to need financial aid, either from rates or from the Exchequer Rate aid would tend to bring into the scheme narrow municipal considerations and would also have the great disadvantage of levying the heaviest burden on the areas least able to bear it In this connexion it is noteworthy that the richest counties have the best hospitals If the grants given were placed in the hands of the divisional and regional councils along with other monies from voluntary sources, contributory schemes, local authorities and so on, the councils would have the necessary powers to carry out their work

Under such a scheme, *since the various hospitals would* be distinguished chiefly by the nature of their work, and since the staffs would be paid and not honorary and each hospital would have an outpatient department the reasons for maintaining any superficial distinction between systems would disappear and it should be possible to merge the two There would then be no need to abolish private consultant practice entirely, but the visiting staffs, being salaried, would have their independence curtailed’ to the extent that they would be obliged to carry out their duties in a satisfactory manner The increasing subsidies and the narrowing of the gap between the two systems would necessarily lead to a fall in voluntary subscriptions, especially if the local authorities claimed a large share in the management of the hospitals they supported, so that before long the voluntary system might cease to exist

THE CENTRAL CONTROLLING BODY

Since opinion is united in advising a regional development, the next big question is who is to control the regions It has been suggested that *no council run on* voluntary lines can do this, especially since the general history of joint boards has been unsatisfactory, nor for the reasons already mentioned and because of the unsuitability of municipal boundaries for this purpose should control be given to the municipalities Control is likely, therefore, to pass into the hands of either the Ministry of Health, as full nationalisation, or of some ad hoc body Mr Somerville Hastings, who takes a Labour view in politics, puts forward the idea of his party *that nothing* short of complete nationalisation of all the medical services will do It is also noteworthy that the Association of Trade Union Approved Societies at their *meeting* in 1939 passed a resolution recommending nationalisation of the hospitals Nationalisation would have these advantages

1 Planned regionalisation could be made efficient A detailed survey could be carried out and the recommendations arising therefrom implemented, *since difficulties* due to local-government boundaries could be overcome

2 Finance would be simplified

3 The hospitals would be subject *to Government* inspection and report, and since all the data would be kept in comparable form it would be possible to compare the work and efficiency of the separate institutions

4 Since the staff would be full time employees, private consultations would presumably take place at the hospitals, so there would be an end to the waste of money *in maintaining* consulting rooms in what are often, sentiment apart, unsuitable premises Another result of nationalisation would be that non medical and nursing staffs would have *more equitable* conditions of service

5 Medical education, both undergraduate and postgraduate, could be planned purely on a basis of making the *maximum* use of the clinical material available, leaving the details to special committees in each area Nurses, whose organisations for joint action are notoriously poorly developed, would have

when expressed in molecular units sulphanilamide 11 3, sulphapyridine 11 9, sulphathiazole 10 6 and sulphanilyl-guanidine 10 micromols per 100 c cm erythrocytes This uniformity suggests that the chemical grouping responsible for hæmolysis is the sulphonamide nucleus common to all four drugs, and that the various substitutions which profoundly alter therapeutic action have no effect on hæmolysis except so far as they alter the absorption or distribution of the compound Differences in absorption and distribution may account for Richardson's finding that cyanosis was produced by sulphanilamide and sulphapyridine but not by sulphathiazole or sulphanilyl guanidine As the dosage of the latter two drugs was increased the proportion absorbed steadily diminished, so that a concentration in the erythrocytes sufficient to produce cyanosis was probably not reached in the limits of Richardson's experiments His work, by drawing attention to the importance of molecular concentration in the red cells in determining the occurrence of hæmolysis, may point the way to the development of more effective compounds with less toxicity

ABSENTEEISM IN WAR FACTORIES

Why do some workers in war-factories stay away from work more than appears, at first sight, to be reasonable ? The employers blame the men and the men blame the employers, and whatever may be the root causes of the trouble (if the word is not a little too comprehensive) it is most important that they should be sought and dissolved in a spirit of harmony Team work is essential for most enterprises and especially for our present one of seeing that the doctrines and practices of the *Herrenvolk* shall not prevail in the world Important visitors to two shell-filling factories have reported[1] that absenteeism is causing considerable dislocation of work From a somewhat limited survey they have arrived at conclusions about absenteeism which appear to be sound and of general application, In the winter absenteeism varied between 15 and 20% , on the adoption of a three-shift instead of a two shift system the figure fell immediately to 10%, rising again later to 12% Women stayed away more often than men and there were always more absentees from the morning shift than from the other two It was not surprising that Saturday afternoon and Sunday morning were the periods more in favour with the workers for taking a rest In one week 26% of the women and 16 8% of the men played truant on Saturday afternoon , 22% and 18 4% did the same on Sunday morning

The main causes of absenteeism appear to be these transport difficulties , lack of adequate living accommodation near the factories , imperfect working conditions, especially the arrangements for getting food in canteens , and, last but not least, the 7-day working week It is pointed out that most workers have to travel three or four miles to work, some of them as much as thirty Without adequate provision of special trains and omnibuses it is idle to expect workers to be punctual or regular The select committee regards it as a primary duty of the Ministry of Supply to see that transport facilities are adequate Hostels should be built near the factories and accommodation provided for the workers at a reasonable cost Continual watch should be kept on canteen arrangements and prices, and the supply of food to factories given reasonable priority The committee finds that the Sunday atmosphere is not conducive to maximal effort " No man," the report says, " can work seven days a week for any length of time and maintain his output, and this is even more true of women " The abolition of Sunday work, except for maintenance or for real emergency, is therefore recommended In the committee's opinion the men appointed to manage the Royal Ordnance factories should have first class abl but it appears that the Ministry of Supply is handicap in its choice by the Treasury scale of salaries A rev of this scale is thought to be an urgent matter clear implication is that the character and personal of the management play an important part in determ ing whether or not the workers stay away from factories for seemingly trivial causes, and indeed i well known that the presence of a bullying foreman manager has the effect of raising appreciably the rat sickness absenteeism Where workpeople are made feel that they are co-partners in an important urgent task the rate of absenteeism falls , it may e be difficult to get them to take holidays—an attit into which the question of wages also enters number of places is diminishing in which the work are treated as if made of inferior clay and even in th that remain there are signs of a change of heart

LUPUS IN EDINBURGH

Fortunately lupus vulgaris is no longer the com disease it was Whether war conditions will produce influx of new cases remains to be seen, but no inci has yet been noted Its treatment is always tedi so that cases tend to collect in the clinics which tak special interest in them One such clinic is at Edinburgh Royal Infirmary, where for a number years Dr Robert Aitkin has spent a great deal of time in treating this affliction He has lately summaris the cases dealt with in his department Two importa facts stand out from his analysis—that 25% of the cas began during school life, and that 50% followed cervic adenitis A big factor in the fall in incidence must b that glands in the neck are now for the most part treated by general light baths rather than surgically But purer milk supply, slum clearance, and regular medic inspection of school children have also helped Th high rate of cures (735 cases out of 957 in the last te years) at the Royal Infirmary is undoubtedly due to th employment of the Lomholt lamp for local treatmen Many of the patients have now been free for as long a six years Dr Aitken urges the need for long continue treatment and careful follow-up, and above all a con tinuity in nursing His figures show that the optimisti outlook which is a feature of his clinic is fully justified

Mr William Gissane has been appointed clinica director of the Birmingham accident hospital and rehabilitation centre and will take up his duties early in September Mr Gissane, a surgeon specialist to th L C C , is at present in charge of the accident unit at St James Hospital and of the fracture unit at Lewisham Hospital The new accident hospital has found a hom in the building of the Queen's Hospital, which closed it doors as a general hospital at the end of March

---

Feathering the Stork's Nest —The Ministry of Health (circular 2437) has arranged with the Board of Trade that after Aug 1 expectant mothers will b given 50 coupons to buy materials to make clothe for their baby before it is born The coupons wil be distributed through the local welfare authoriti and will be issued on the production of a certificate from the doctor or the midwife booked to atten the birth If the mother is attending an ante natal clinic the certificate should be signed by th medical officer of the clinic The Ministry of Healt urges that the coupons should be supplied as soon as th likelihood of birth can safely be assumed and sugge that this will usually be in the sixth month of pregnanc Where a diagnosis of twins is made and confirmed t mother is entitled to 100 coupons The doctor's ce ficate should state the name and address of the expect mother , her national registration number , and approximate date on which the confinement is expect

---

[1] Seventeenth Report of the Select Committee on National Expenditure London H M Stationery Office 1d

[1] *J phys Med* 1941, 4, 68

The hospitals, when merged into one system, would ise a monopoly The assets would be national

The day-to day running of the hospitals would be in the ls of the local, divisional and regional committees The d would carry out general lines of policy for which the ster of Health would be responsible An annual report, m up so as to give some real information and not to act cloak, would be published, and Parliament would be able ise questions of policy when the financial vote was under nderation

The board would be a small one with not more than ten abers with full executive powers They would be chosen the Minister of Health and would be mostly experts—lical, nursing and lay with some representation of medical hing Advisory committees would be set up by the board deal with such special aspects as clinical education of dents, finance, nursing and so on The directors could be ointed for a fixed period, made variable so as not to permit rastic change and removable, say, by the Prime Minister the Minister of Health acting in the name of the Privy ncil, as in the B B C

Regional development would be encouraged and regional ncils would have a measure of freedom Data would be ected in a standardised form and a report made annually the working of each unit and each region Visitors, lical and lay, would carry out inspections to ensure that easonable standard was maintained and to give the advice ich only people with authority and a detached outlook give

The board would have to be more in touch with the public m is the B B C , whose governors, at all events until lately, l not represent a cross section of public opinion, and there uld be scope for an advisory committee representing tients' interests, without executive power but with access the board In each of the corporations so far established has been difficult to maintain a desirable degree of independence without allowing an excessive remoteness from all public ntrol

7 Staffing of such a service would probably be on general ivil Service lines, but with the promotion on merit which at esent exists in the public corporations

A board of this type, provided that nationalisation is und to be necessary in order to secure coordination, ould be in a better position to maintain the essential atures of the voluntary system than a special depart-ent of the Ministry of Health, and would at the same ne allow of some local autonomy

TWO OTHER PLANS

The work of the University Grants Committee has led the suggestion that grants to hospitals might be dis-nsed by a committee working on similar lines and so der nationalisation under either a Government depart-nt or a public corporation unnecessary The com-ttee consists of a full-time chairman, eight part-time mbers and a secretary, and it has the task of advising Government as to the application of grants made by rliament towards the cost of university education e committee has full discretion in allocating this ney and can make any inquiries which would help it form an opinion, but it does not interfere in internal nagement or attempt to cramp the freedom in which iversity education flourishes Needless to say, gross fficiency would lead to forfeiture or reduction of the nt The objection to control of this kind, which is ular to that exercised by the King's Fund for the ndon voluntary hospitals, is that although it would applied, through the divisional and regional councils ere would remain two parallel systems It is doubtful o whether the mechanism would be strong enough to ercome the difficulties in the way of coördination which ve been described, and as far as hospitals are concerned re would still be no national policy nor would the spitals be an intrinsic part of the public-health services, ich is most desirable

Robson, in his book on the Development of Local vernment, suggests another possible alternative to ionalisation By the Education Act of 1902 volun-y schools receive rate aid in return for a measure of trol by the local authority, who have the power to oint two of the six managers The teachers are pointed by the managers, but the local authorities can o the appointment on educational grounds, and local horities have the right of inspection and of regulating secular education The voluntary schools maintain the fabric of their buildings but the local authorities pay the teachers and provide the stationery As applied to hospitals such an arrangement would mean that in return for substantial rate aid local authorities would have considerable representation on the boards of management of the voluntary hospitals and might in certain circumstances exercise a deciding voice in policy If applied to a regional scheme, this plan would imply the setting up of special joint boards of local authorities, which have not up to the present been a conspicuous success Moreover, just as the arrangement permitted the continuation of the disagreeable feature of having two systems of elementary education, a similar one would retard the development of a coordinated hospital policy

Neither of the last two schemes seems to me to have the advantages of a well chosen, strong, semi-independent national hospitals board

---

MEDICINE AND THE LAW

Overdose of Local Anæsthetic

THE fatal administration of a local anæsthetic ten times stronger than the intended dose was investigated at an inquest lately held in Bath A patient suffering from gallstones was advised to have an operation A solution of Decicain was injected as an epidural anæsthetic The honorary anæsthetist at the hospital asked the sister for a 0 1% solution, telling her that it was to be used for a nerve-block By a regrettable misunderstanding the theatre sister thought that a 1% solution was asked for After the injection the patient had a convulsion Oxygen was given and artificial respiration was applied , an antidote to the decicain was injected and there was an injection of adrenaline into the heart , the heart was massaged In spite of these efforts the patient died The coroner's jury found that the overdose had been accidentally administered and attributed no blame to anyone The coroner suggested that, to avoid such errors, the proportions of the drug should be prescribed in writing This might fix responsibility as between the medical man and the sister, but even written instructions are not proof against human fallibility

Defective's Claim for Illegal Detention

In Innes *v* General Board of Scotland a mental defective's claim for £1000 damages on the alleged ground of illegal detention failed in view of the time-limit prescribed for such actions by the Public Authorities Protection Act Innes had been received into the Baldovan Institution on an order dated May 11, 1932, which expired on June 30, 1933, and which was not validly renewed in terms of the 1913 Act His mother repeatedly requested his release and eventually took proceedings whereby the court held the order for detention inoperative after June 30, 1933 The General Board for Scotland appealed unsuccessfully, and it was found necessary to deal with this kind of situation by statute in March, 1940 There was no doubt that the continuance of the detention had been justifiable on medical grounds, but courts take a strict view in cases where the liberty of the subject has been infringed It may be recalled that the same point arose in England in the Winterflood case in 1938, when the position also required the attention of the legislature The English act of 1913 contemplated that the order for detention of a mental defective should expire at the end of a year but could be continued in the patient's interest after examining medical experts and certificates In the Winterflood case there was a gap between the date of expiration and the appropriate date of renewal it is easy to understand that institutions concerned with hundreds of patients cannot always make sure of synchronising the two dates Parliament then passed a law to allow a margin of time to cover these administrative steps The statute for Scotland in 1940 had the like effect When, however, the action for illegal detention was launched recently in the Innes case, it was clear that it was not begun within six months of the date when the wrongful detention ceased This six-months rule, enacted by the Public Authorities Protection Act of 1893, was a bar to the claim against the Board of Control regional and divisional representatives to watch their interests, and this would lead to a levelling of some of the glaring inequalities in the conditions of service

Against these undoubted benefits must be set some probable disadvantages

1 The voluntary hospital system has a long and honourable history Its units are independent and proud of it, and while this has led to rivalry and overlapping it has also kept the more progressive units in close touch with the advances in medical knowledge, since their prestige largely depends on their ability to convince the public of their prowess This is probably less true of the non-teaching hospitals, and still less true of the very small units The system of choosing the honorary staffs and the competitive element in private practice has helped to maintain keenness, since success in private consultant practice is based on the reputation gained in the hospital wards and outpatient departments Some oppose nationalisation because they believe the competition of private practice to be eminently desirable Others fear that nationalisation will bring with it the dead hand of excessive central control, with a rigidity of outlook and the loss of the conditions under which medical teaching and research have flourished , if the hospitals alone were nationalised, without a full state medical service, this great danger would be lessened, but it is likely that, as has happened in New Zealand, one event would soon be followed by the other A criticism of the Emergency Hospitals Services is that there has sometimes been *a failure to take full advantage of local knowledge* , all questions of moment are referred to Whitehall so that the regions are by no means autonomous and the scheme is in reality highly centralised Centralisation of this type, often unimaginative, taking no note of local conditions and local feeling, and perhaps in the administrative charge of people with no special knowledge of hospitals would be deplorable

2 The cost of the nationalised hospitals would be high, since, apart from the extension of their work which would undoubtedly follow nationalisation, the medical, nursing and lay staff would no longer be expected to work for unreasonably low wages On the other hand, the economies effected by the regional and divisional mechanism, including the saving on bulk purchase, a pooling of equipment and the closure of inefficient units, might be considerable The bill would be paid largely out of forced contributions from all sections of the community, most of it as at present coming from the higher income groups If the hospitals were financed on an insurance basis, on the analogy of the War Damage Act, the healthy would pay towards the cost of the sick and people would no longer have to carry the financial burdens of illness at a time when they are least able to bear them

3 Whole time government service tends to stifle initiative for several reasons (1) Government departments do not usually punish for bad work but may refuse to promote (2) Salary scales are more or less automatic and there is not sufficient inducement to staffs to improve themselves and the service (3) Promotion is to a large extent by stepping into dead men's shoes, since most Government grading schemes make little allowance for exceptional ability (4) The staff are often remote from the central department which recommends promotions

On balance the disadvantages of running the hospitals as a department of the Ministry of Health seem to outweigh the advantages, since it is probable that sufficient attention would not be paid to the merits of the voluntary system and there would be a tendency to excessive rigidity and over-centralisation

GROWTH OF PUBLIC CORPORATIONS

Since neither municipal management nor direct management through a Government department appears to be satisfactory and joint boards have many disadvantages and are difficult to get working efficiently, the suggestion that hospital management might be in the hands of an ad hoc board, moulded on the general lines of the boards at present managing some of the public utilities has been much discussed

One of the most remarkable developments in administration has been the growth of the public corporations The idea dates back to the old Improvement Commissions and Turnpike Trusts, which were gradually changed into Government departments or merged into the local authorities Three of the present bodies, the National Health Insurance Committee (1912), the Road Board (1910) and the Port of London Authority (1908), were in existence before the last war and more rec
the following have been added

Forestry Commission (1919)
British Broadcasting Corporation (1926)
Central Electricity Board (1926)
Coal Mines Reorganisation Commission (1930)
Area Traffic Commission (1930)
London Passenger Transport Board (1933)

These public corporations supply such impc
needs that state regulation is necessary and yet
enjoy a greater measure of independence than a
state department can provide They are also in
touch with the public than a state department
is and are not dependent on the political comple
the Government They have been popular becaus
are a compromise which people of various political
can accept They are run by the national auth
but their ability to collect capital from private
and to pay interest gives them the support of uph
of private enterprise , also they are fairly free
political interference

The Post Office is often quoted as showing that a
department can carry out these functions equally
but it is significant that the changes considered nec
after the Bridgman Report were all in the direct
the organisation seen in public corporations The
corporations mentioned have the following featur

1 They all control important services which must
on business lines but must be responsible to the public

2 They all have virtual monopolies

3 Their revenue and expenditure should at least b
so as to ensure financial independence, while loans at lea
subject to Ministerial sanction

4 Except in the case of the Forestry Commission, men
of Parliament are not allowed to sit on the boards

5 They are responsible to a minister and he is answer
for them in Parliament, but he will not answer questions
the day-to day running of the services and so Parliament
control is remote This tends to remove the excessive cau
sometimes associated with Government departments, w
are extremely sensitive to Parliamentary criticism

6 There is public ownership and control of the a
The assets of the B B C are entirely owned by the corp
tion , those of the London Passenger Transport Board
vested in the community

7 The boards usually consist of between five and e
members of which one or two are full-time and the rest
time They are usually appointed for a fixed period but
always for the same period, so as to ensure continuity
directors of the B B C can be removed by the Privy Cou
those of the Central Electricity Board only by Parliam
Generally speaking, the boards are set up by the minister
not directly elected Except in the case of the B B C
members are mostly experts and power tends to be in
hands of the senior paid official

8 The Port of London Authority is composed larg
consumers' interests, since there is a compact and o
body of consumers, while the consumers' interests in
B B C and Central Electricity Boards are represented
through advisory committees

9 Parliament has a general control of their policy and
tainly has the direct ultimate control, since it can al
remove what it has set up

10 Conditions of service vary much in these different
porations and are not the same as those in the Civil S
In the corporations it is easier to secure reward for ment
promotion may be rapid

A NATIONAL HOSPITALS BOARD

When the hospitals are considered in the light of
points a good case can be made out for setting u
National Hospitals Board It is presumed that org
tion would be on a regional basis, probably run by
sional and regional councils having many of the fea
suggested in the Nuffield Trust Scheme While h
administration cannot be described as a comm
enterprise, many of the features in the list given w
apply

1 The hospitals form an important public service
should be responsible to the public Much of the
this service should be on business lines and a well const
board would give the amount of flexibility which is as
for that service as for a business enterprise

e has been held up as rather more than a snob for not king the Jordan baths Do we know all the facts? Some time ago a patient of mine with hyperpiesia went up to see a specialist who later wrote him a letter which I saw After recalling rather in the manner of prosecuting counsel that his father died of cerebral hæmorrhage at the age of 72 and his mother of cancer at 70, he went on to state unhesitatingly that the patient was born with, had been suffering all his life from, and was still suffering from the results of intestinal toxæmia A strict regime was prescribed, no meat, eggs only if absolutely fresh, and on no account must anything be cooked in an aluminium utensil Taboo to tobacco and alcohol, fie on all gluttony He must come up and have a course of colonic lavage and osteopathic manipulations, he must have intramuscular injections and take pills of two kinds, further a salve will be sent to him and a vaccine made from the flora of his intestines Woe to him if he follow not the precepts of this prophet, but if he does he may yet walk among the blessed How do we know that Naaman hadn't received some such missive from the hydropathic establishments on the Abanah and Pharpar?

The certificate menace grows apace Owing perhaps to the increasing mistrust spread among us by the Little Lad over the water, panel patients now seem to require not only N H I certificates but also sundry additional slips of paper to show to various interested parties such as employers, insurance companies and so forth Among the newer types of official certificate is one, inappropriately coloured yellow, for those injured in air-raids When the stout-hearted victim is doing his best to recover from half a dozen fractures and various blast injuries it seems a trifle redundant that he or she should have to be re-certified unfit for work as often as once a week, a monthly certificate would save paper, ink, postage and—what is seldom considered by the official mind—the doctor's time The conscription of women has given rise to an entirely new type of certificate which has not yet attained the dignity of print and has to be written out in full

> Mrs (or occasionally and most regrettably, Miss) , being x weeks pregnant is at present unfit for any other kind of national service

Tempora mutantur The time-honoured boast of the sergeant-major that the army can do what it likes with you except put you in the family way no longer needs even that qualification

* * *

Last night dear Percy, our mess bore, was holding forth on how Nature thought of everything first, the hypodermic syringe of the mosquito, the smoke-screen of the cuttle-fish and so on, when one of our younger members, tiring of these immense profundities flippantly interjected, "What about an air-gun?" But, of course, Nature does have a most excellent air-gun, whose missile provides the air which onrushing peristalsis compresses Not only does her ordurous pellet give off gas behind itself, where being more compressible it acts as a pusher, like the back rows of the scrum—sometimes slipping round, I suspect, and getting off side when the muscle-tone is slack, for which we pay a costive penalty—but it also gives off gas in front which, like the pilot engine before a royal train, or the bag of waters in labour, goes forward to clear the course A dozen aspects of this entertaining mechanism present themselves—how in the upright position gas will tend to accumulate at the hepatic and splenic flexures sort of ammunition dumps, how this air-gun is held as all guns should be when not in use with barrel pointing downwards, how at the moment of discharge the barrel becomes nearly horizontal—or would be if the Jove-aping dignity of man and the closet-designer allowed Is it likely that Nature wouldn't utilise a product she can't help forming? Yet there is little in the textbooks about it Isn't it important enough? It is of vital importance to king and cowherd Then there is the comparative anatomy the machine-gun method of the rabbit, the bomb of the herbivore, the torpedoing of man What a subject for a thesis, "The Aerodynamics of the Intestine"!

Parliament

Priority for Milk

In the House of Lords on July 15 Lord DAWSON once more voiced his anxiety about our milk supplies for the coming winter The production of milk is like a reputation, very easy to lose and difficult to regain, and unless we are to face a curtailment of our milk we must act at once The cow gives us more value for our money than any other animal, the egg-producing fowl and the pig coming next, and they all deserved special consideration But apart from their high nutritive value milk, cheese and eggs helped enormously in the preparation of winter foods such as cereals, potatoes, carrots, beans and even onions Indeed it was almost impossible to think of cookery in this western world without milk and eggs Lord Dawson congratulated the Minister of Food on the improvement in the cheese position and on his store, actual and prospective, of preserved milk Lord Dawson further urged the manufacture of sprayed whey powder, which could be prepared from waste products In designing our food we must be influenced by neither prejudices nor interests, and give knowledge pride of place

The Duke of NORFOLK's comforting reply on behalf of the Ministry of Agriculture that dairy herds in this country are increasing, lost some of its reassurance when he admitted that next winter there may be a slight shortage of milk Lord DAVIES reported the incidence of a new infectious disease—the black market instead of the black plague—and the discussion which followed was enriched by a wealth of controlled reminiscences and shopping sagas The House felt sympathy with Lord WOOLTON when he confessed that he found it extraordinarily difficult to retain a proper sense of perspective in dealing with food Complacency was the latest of modern crimes, but he felt that no-one without the skin of a rhinoceros could be complacent as minister of food At first he had been inclined to think that the public were the best judges of whether they were being adequately fed, but before the war there was no acute consciousness in this country that so many hundreds of thousands of people were suffering from malnutrition The country has become more sensitive to this issue during war-time than ever it was in peace, and it is good that it should be so Yet he would venture the speculation that there are fewer people suffering from malnutrition now than two years ago Food is certainly more equitably distributed than it was then This year the nutritive values of foods have declined, but next year they should be as high as they have ever been in the last 15 years He was hoping for some improvement in the variety of the nation's dietary, which partly explained the new yellow ration books During the winter he had no doubt that with the help of New Zealand and the United States we should secure all the milk that we required in one form or another for the National Milk scheme, for children, for adolescents and for invalids

A Stepping-stone

The scanty attendance at the second reading of the National Health Insurance Contributory Pensions, and Workmen's Compensation Bill showed that at least the House found nothing objectionable in the measure Indeed they welcomed it, with some exasperation, as far as it went, but that was not nearly far enough Second-reading debates, as Mr BROWN said, give members who have long-cherished ideas and ideals opportunities to get their dreams a-going, and the debate on July 15 demonstrated a tepid approval of the bill but a strong disquiet at the glaring discrepancies in our present system of social insurance People with the same need receive different benefit, the sick breadwinner and his dependants are treated differently from the unemployed worker and his family, the disabled man and the disabled woman do not receive equal help, benefits vary from one approved society to another, some insured people have difficulty in finding any approved society to accept them Mr GRAHAM WHITE spoke for the House when he said, "Let the bill be passed as soon as may be, and let us concentrate upon the wider proposals to follow the deliberations of the Beveridge Committee"

The bill which was introduced on the 29th birthday of N H I by Mr T JOHNSTON, proposes an increase of

In England Now

A Running Commentary by Peripatetic Correspondents

WHEN Russia was attacked Mr Churchill lost no time in declaring that this made no difference to our objective which was, is, and always will be, the crushing of Nazi Germany The bulldog has his teeth into the dachshund and no poodle, peke nor macaroni hound shall pull him off, nor will he loosen his grip to consider what the other end of the dachshund is doing Would to Heaven we had a like clarity of view in our fight against tuberculosis Who is our enemy ? The bacillus tuberculosis ? Surely not Would we abolish it from these islands if we could ?—and have a rising generation perpetually Pirquet negative, defenceless against attack which would inevitably come in time ? And if we don't know who is our enemy, neither do we know who is our friend, who it is that gives most of us immunity—the mildly infected cow, the pooler of milk, or the ambulant spitter who sprays the streets with his saprophytic guests ? Until we do know, the host of T O s, health visitors and whatnot is an army without an objective, hesitant Sometimes though rarely the enemy is fairly clear Recently in an isolated community in the west of England two cases of tuberculous meningitis, several of pleurisy, a crop of adenitis occurred in the children attending the state school, where it emerged a schoolmistress with a liquid cough was disseminating the seeds of death with the *rudiments of learning* *And that is only the first harvest*, for tubercle has two incubation periods—very roughly of three months and twenty years—and a long time must elapse, and memory fade, before the second harvest is gathered to the grave Even here we don't know whether the catastrophe was due to the quantity of bacilli that were sprayed over the children or their quality, their virulence Suppose the schoolmistress had been an old woman, who had had tubercle for years, and harboured what to her was an almost harmless bacillus, would she have vaccinated the children against a robuster germ, and been a benefactress ? I dunno, but until we know these things the fight is feckless

* * *

One of the things which like the profession of medicine appears to be due for a complete overhaul after the war is our national system of education It has received some hard criticisms, more especially from those who have passed through the prep school to public school and university curriculum It has been said that the system tends to turn out everyone cut to a pattern and that many of its products are tainted with at least some trace of totalitarian doctrine People seem to forget that though you can take a horse to the water you can't make him drink In fact if you take him too often to the water the horse may develop a loathing for water and a taste for beer, like the horses in the all-night beer gardens of Hamburg which the R A F presumably have now laid low In more medical language the pedagogue may easily produce immune bodies against the doctrine that he wishes to inculcate In my own case a healthy distrust for all authoritarian doctrine was first inculcated in me by one of the masters at my prep school who when he was not telling us of the virtues of compulsory games was expounding the duty of loyalty to the cricket captain Even at that early age I had a suspicion that compulsory games were encouraged (they are a post-Arnold development) rather for the convenience of the masters than for their positive value to the boys, while as for loyalty to one's cricket captain it was of the same order as " theirs not to reason why " however big a boob one's captain happened to be All the same, my early training or immunisation has been of great value for after all " das Fuhrer-princip " *is nothing but loyalty to* one's cricket captain writ large, while a belief in the mystical value of compulsory games is in all respects equivalent to a belief in the philosophical values arrived at in a hypothetical nordic stone age Nevertheless the curious thing is that however much one may loathe the totalitarian system it is very hard to loathe the individual totalitarian

Letters to the Editor

PREMARITAL AND PRENATAL TESTS

SIR,—In this country it has always been found to be e policy to avoid legislation which is in advance of blic opinion Public opinion would almost certainly in opposition to legislation on American lines enforcing assermann tests, but it would probably raise no jection to such tests being carried out as a routine pregnancy if obstetricians recommended it Medical inion carries great weight—more weight than we rselves often give it credit for. In our prenatal clinics is not the expectant mothers who object to blood- ts, it is the doctors in charge of the clinics who still se objections to their routine performance During e last five years, over 4000 specimens of blood for amination have been taken in the Kensington clinics thout the slightest difficulty In fact, some patients mment adversely on other clinics where the investiga- ons made are less complete.

As your leader of July 12 aptly puts it, any case of suspected syphilis discovered and treated is a gain the nation. It is a pity that the routine performance Wassermann tests, which had been slowly gaining ound, has been discontinued by some hospitals during e war ; the tests are more necessary now than ever, d the idea of blood-testing and transfusion has become popularised that there can be no difficulty in obtaining ie blood for examination. As the adjunct to a full renatal overhaul and as a routine measure carried out every case without exception, it can have no bad sychological effect on the individual patient Public pinion is now bringing expectant mothers to private doctors, clinics and outpatient departments early in pregnancy ; the issue of milk at a cheap rate is encouraging this tendency All things seem ready for the institution of a routine prenatal blood-test throughout the country if the obstetricians would agree among themselves to establish the principle Experts in venereal disease would be repaid by the lessened incidence f congenital syphilis

A premarital test represents a new idea, hitherto alien o Britain, and the question needs to be considered in all ts aspects It is a much more difficult question than he prenatal test Most of the expectant mothers with ositive blood reactions in the Kensington series of cases ave either been latent cases of long standing or congenital cases , in only one or two instances was the infection recent one. By intensive treatment during pregnancy ne has had a reasonable degree of confidence that the aby, apparently healthy at birth, will remain healthy he question at issue is whether, if the mother's positive est had been discovered before marriage, a better or ven as good a result would have been obtained Would he marriage have been cancelled ? Some of them have een happy and successful marriages and surely a ist-minute cancellation for such a reason would cause vere psychological trauma to both parties ? It would e an unenviable task in any case to inform the bride- room within a few weeks of the announced wedding at his prospective bride was a congenital syphilitic the best of circumstances one feels that a shadow of isease and possible guilt would be thrown over the arriage, and it is conceivable that it might have the fect of causing the wife to try to avoid a blood-test, ould she become pregnant, instead of seeking early eatment It is certainly much easier for the doctor break the news of a latent positive test in the mother oth to her and to her husband, tactfully, and without ndue psychological reaction, when they have already een married for some time

It is possible that arguments as strong or perhaps stronger might be raised to support a test before marriage, and many of us still feel that we are waiting to be convinced on the matter Should the desirability of a premarital test be established, it should be brought about voluntarily by the introduction of premarital clinics where tests could be taken, rather than by attempted legislation

It would seem a pity to restrict the function of a premarital clinic solely to the performance of Wassermann tests which after all only affect a small proportion of the population A short routine examination on life insurance lines would seem of definite advantage, both to the prospective couple and to the state From the sociological as well as the medical point of view such clinics, which have often been proposed present interesting possibilities on the psychiatric side For most couples no advice would be necessary and the doctor would only need to wish them luck In other cases, however, much good might be done by answering questions and relieving doubts The whole subject seems worthy of discussion as a part of postwar reconstruction

Kensington VIOLET RUSSELL

URINARY DISINFECTION

SIR,—Your leader of June 28 mentions the use of small doses of a sulphonamide in the control of urinary infection. In Helmholz's case a dosage of 0 125 g of sulphathiazole twice daily had succeeded over a period of seven weeks, in keeping a chronic and apparently incurable infection in check, without causing any general toxic effects There are records of other cases successfully treated over much longer periods, in which the drug used was given at a rate half of that employed by Helmholz As far back as March, 1940, a Cape Town urologist told me of a middle-aged woman patient with normal excretion, whose *B coli* infection had been controlled for over eighteen months with doses of 0 25 g of sulphapyridine taken once every forty-eight hours The experimental omission, on a number of occasions of several doses had invariably been followed by a return of the bacilluria A Brisbane pædiatrician subsequently showed me the notes of a similar case of a child where the same drug and the same dosage was employed

The administration of such small quantities of a sulphonamide appears to be attended with none of the symptoms of intolerance (gastric upset, mental depression, dermatitis, and damage to the kidneys or blood-forming organs) recorded with the higher dosages ordinarily employed , but proof of this can be obtained only after prolonged observation of a large number of cases In the selection of the appropriate drug and dosage regard must be paid to bactericidal power and to rate of excretion Sulphathiazole appears to be the most active of the sulphonamides in common use but, on account of its more rapid rate of excretion, it seems unlikely that one dose repeated every forty-eight hours would be efficacious Whichever drug is used in such minimal amounts, it is certain that the concentrations attained in the body fluids must be very low One is tempted to ask what effect this light dosage may have on rendering bacteria drug-fast

Dagenham Essex. ROBERT FORGAN

"SCIATICA"

SIR,—Foot-trouble as a possible cause of sciatica has not been mentioned in the present series of letters, although well known by many A short note of three such cases will help to emphasise this point

CASE 1 —In 1931 a woman of 37 started pain in the left buttock, thigh and leg The pains occasionally shifted to the area supplied by the anterior crural nerve Treatment, including an energetic course at Bath, produced only slight temporary improvement, followed by exacerbation of the sciatic pains, so that the patient became almost crippled I suggested a trial of an instep-arch support owing to extension of pain and tenderness to the left foot I thought that metal or other hard substances, which could not be altered in shape or thickness, ought to be avoided Having decided to use thin wedges of sole leather I found that Messrs Freeman, Hardy and Willis stocked the kind required. It consists of a special form of insole with compartments into which thin wedges of leather can be inserted. The front compartment

lice, owing to the fact that they do not desire any publicity, d feel it may reflect on the child's future As regards cases lmitted to the clinic, but not reported directly to the police, action is taken It is very difficult to obtain histories, d in many cases parents or guardians are reluctant to give formation It is considered to be undesirable to press iestions, lest the children fail to return for treatment, as has ppened on previous occasions

3*s* a week in the sickness benefit—memorable since for the first time men and women are to receive an equal increase—and the disablement benefit is to be increased by the same amount Further, the bill provides a new income-limit of £420 per annum, which will bring in something like 500,000 more people. The income-limit under the Workmen's Compensation Act will also be raised to £420 There will be an increase of 2*d* in present premium of 3*s* 6*d* for men and 2*s* 11*d* for women, 1*d* to be paid by the contributor and 1*d* by the employer In future the public-assistance authorities will be prohibited from taking into account the first 10*s* 6*d* of national insurance benefit The changes under the bill will begin in January next year Mr Johnston explained that the panel doctor's capitation fee will be increased, but the amount plus a mileage grant is still under consideration

Mr James Griffiths said social insurance had its roots deep in nineteenth-century life and welcomed this expansion He warned the House that we might not have so long to build up a peace economy as we had taken to build up a war economy Part of the trouble at present was that the workers were thinking of the past and the employers of the future Dr H B Morgan as a former insurance practitioner criticised the working of what he dubbed an elementary medical service There were no hospital arrangements or facilities for pathological and biological investigations The poor general practitioner working in an environment of disease, bad housing and dietetic ignorance, was told to sift cases but was given no proper facilities for diagnosis Dr Morgan had left insurance practice disappointed and disillusioned No doubt the Minister had acquired some medical knowledge by inoculation but Dr Morgan had been hampered in his work at every stage by the administration of medical services under the Ministry of Health He urged the Minister to deal with these men in a spirit not of bureaucracy but of decent humanity, giving consideration to the difficulties of their job

Mr Ernest Brown in summing up said he did not want Dr Morgan to think that he had overlooked that there was more than a cash side to the insurance scheme There was a medical side too, and he was sure that one of the things that the Beveridge Committee would have to consider was how the doctors, the public and the state could get the best, from the point of view of preventive medicine, out of the provisions that had been made, or might be made in the future

The Pharmacy Bill in Committee

The House of Commons when it examined the Pharmacy and Medicines Bill in committee, on July 15 and 16, made no great changes in it The Government accepted an amendment to clause 1 moved by Captain G S Elliston making it unlawful for any medicine to be compounded in branch businesses belonging to chemists unless there was a registered pharmacist in charge

Clause 3 provoked a lively discussion Dr Russell Thomas welcomed it as a sign that Parliament was taking an interest in the advertisements of medicine, otherwise he believed it to be futile in that it would not affect the patent medicine trade, the list of diseases defined was meant to be impressive, but sufferers from diabetes would use patent remedies until the disease was diagnosed, and there was nothing in the Bill to prevent a person using all sorts of eye-drops until cataract was diagnosed Mr H Strauss asked if the clause was directed against any advertisements in existence If not it looked as though it was not the best way of dealing with an actual evil It would be better to make it a criminal offence to publish a false statement in connexion with the sale of a medicine Miss F Horsbrugh said that the diseases specified in the clause were among those included in the recommendations of the Select Committee of 1914 Two more had been added She assured Captain W F Strickland that there was no intention to make any difference between municipal and voluntary hospitals If there was any doubt as to whether all the hospitals were covered the point would be re-examined Dr H B Morgan said he was in favour of the bill as a whole but he was not sure that this was not a most dangerous clause Would a doctor who had been struck off the register for some minor offence be unable to advertise some cure which he had discovered, or was he only to be allowed to do so with the sanction of Ministry of Health ? He claimed that such a man be allowed to exploit his discovery, to advertise it and keep it secret if he wished to do so Miss H said that if a doctor who had been struck off the made a discovery he could communicate it through people such as members of Parliament and local a ties The clause was agreed to

Mr. James Griffiths was anxious that the compo tion of medicines should be stated in English E Brown said that it would be difficult to describe eve preparation sold as a medicine intelligibly except t nation of pharmacologists The ideal would be every single thing used in the making up of the should be described in such simple English terms Shakespeare might make a poem out of them Robert Bird appealed for quantitative disclo Prof A V Hill sadly remarked that the art of descriptions in unintelligible terms had been developed Mr Brown promised if the House w accept his amendment of " accepted scientific name other name and descriptive of the true nature " at stage he would re-examine the matter before the rep stage, and his offer was accepted

Sir Thomas Moore's amendment to exempt h from defining the compound parts of their prep was turned down with some firmness An ame by Captain Elliston extending the date when the would come into operation from January, 1942, to J 1942, was accepted

Three new clauses were moved Mr Brown's prop that inspectors under the Food and Drugs Act sho enforce sections 3, 4, 5 and 6 of the Act was added to bill Further discussions on what Mr Brown called t professional and technical enforcement are proceedin Sir E Graham-Little, after discussion, reluctantl withdrew his proposal to forbid the sale under a fanc proprietary name of a preparation listed in the B P or B P C, when Mr Brown pointed out that th innocent-looking proposal would make the measure int a new bill Sir Dymoke White's clause restricting th distribution of new proprietary medicines to chemist was turned down

QUESTION TIME

Additions to our Food

Mr G Mander asked the Parliamentary Secretary to th Ministry of Food into what form of food the minimum dail requirements of the most important vitamins and mineral were being introduced, whether he was aware that th United States of America were anxious to send us syntheti vitamins occupying negligible shipping space, and whethe advantage would be taken of this —Major G Lloyd George Steps are being taken to obtain from the U S A such quan tities of vitamins as are desirable to supplement the amount available in the form of natural foods Medical and scientifi advisers consider that the only mineral deficiency which to be feared under war-time conditions is calcium Recom mendations for dealing with this possible deficiency are no under consideration In answer to a further question fro Mrs Rathbone, Major Lloyd George promised to giv speedy consideration to the addition of calcium in both whi and wholemeal flour bread

Venereal Disease in Jamaica

Dr H B Morgan asked the Under Secretary of State f the Colonies whether he was aware that a visit of inspect paid to the venereal disease clinic in Kingston, Jamaica, ha revealed that, amongst the patients found awaiting appro priate treatment, were two young girls, seven years of age that these children were diseased not by hereditary infectio but by direct contact, how many such cases existed i Jamaica, and what steps had been taken or were bei taken to ascertain the perpetrators of such crimes with a vie to punishment —Mr George Hall replied I have n knowledge of the two cases mentioned, but, although n definite figures are available, the medical officer in charge o the Kingston clinic estimates that a quarter of the childr attending the clinic are infected by direct contact Th governor reports that cases are from time to time reporte to the police who press the charge, but that such cases ar very difficult to establish In many instances where a chil is infected, the parents are very loth to give information to t

Continued at foot of opposite page

lown into subgroups, it is not surprising that the chief predilection for private attendance was among those with higher incomes, but even among these a state service was preferred to extension of the panel system The questions posed may have been unduly simplified, and he validity of the survey is subject to the usual errors of ampling, but such surveys are being relied on to a onsiderable extent both in the U S A and more recently n this country as a gauge of public opinion It seems justifiable to regard these results as evidence that the general public believes that the present medical services are not satisfactory and that a state service would be advantageous, particularly for its less wealthy sections

CLINICAL RESEARCHER

Public Health

Medical Care for Norfolk Evacuees

ON July 1 a scheme was introduced in Norfolk for the home treatment of accompanied children, mothers and other adults evacuated to reception or neutral areas in that county Dr T Ruddock-West, county medical officer of health, drew up the plan of campaign which has been approved by his council and the Ministry of Health Briefly the idea is to pay a quarterly capitation fee of 7*s* 6*d* to district medical officers for each evacuee they attend at the request of the relieving officer This fee is to cover travelling expenses and the usual medicine and appliances provided under national health insurance, but where an illness involves continuous attention for more than three months 30*s* will be paid, whether the illness continues over the whole year or not Back payment is to be made to the district officers for the work they have already done and as some doctors may not have kept records of their evacuee patients the payments will be assessed in proportion to the claims submitted next September at the end of the first quarter

Beginning at the other end the scheme works equally simply Evacuees will apply to the relieving officer in the usual way for a medical order and on application to him will receive a combined evacuee medical order and report form to cover the current quarter The patient takes this form with him and the medical officer keeps the order until the end of the quarter, recording the date of each visit or attendance at his surgery on the back of the form No fee will be paid unless the claim is supported by the completed medical report, and in cases of acute illness where a patient is seen before a medical order has been made out the appropriate forms should be obtained forthwith from the relieving officer The scheme does not of course cover unaccompanied children for whom the Ministry of Health made provision (circular 1882/1939) through the local medical emergency committees

From the Annual Reports

STOCKPORT AND PRESTON

Dr John Yule reports that in Stockport 583 out of 1833 deaths, in 1939 were certified as being due to heart disease of which 412 were over sixty-five Of 177 men and 277 women who had survived their seventy-fifth year, 85 men and 133 women were certified as having died of heart disease and 29 men and 50 women of other circulatory disorders Only 6 male and 17 female deaths are referred to senility, but with the exception of 13 male and 18 female deaths from cancer, 2 male suicides and 3 male and 10 female deaths from accident, it would not be amiss had all the rest been attributed to senility Similarly in Preston Dr F A Sharpe reports that, of 1435 deaths at all ages 802 were of people over sixty-five, of whom 365 were certified as having died of heart disease and 107 from other circulatory diseases, 24 people over seventy-five had their deaths attributed to senility, but, excluding 14 deaths from violence, 23 rom cancer and 2 from peptic ulcer the remaining 310 might also have been ascribed to senility

All death tables of recent years show two great shifts rom those of the past—a steady increase in the proportion of deaths over sixty-five, and in those attributed to heart disease This does not mean that heart disease s increasing, or that people with diseased hearts live onger than they did formerly, but that the potential ife of the heart determines the length of our existence, and as the adventitious causes of death are reduced or eliminated more of us die from the natural failure of our potential In neither town was there any fatality from heart disease in children under five years, and only 21 in Stockport and 10 in Preston in people under forty-five

CHINGFORD

This borough is on the extreme fringe of London, it is mainly residential and has not grown with the rapidity of Ilford The population is 39,460 and in 1939 it had a birth-rate of 16 9 the very low infantile mortality of 22, crude death-rate of 6 8 (comparable rate 7 8), and maternal mortality of 1 5 with one death only none from puerperal fever Its cancer death-rate was low for such a unit (1 2) made up of 48 deaths, of which 22 were from cancer of the gastro-intestinal tract, 4 of the lungs, 6 of the breast 8 of the genito-urinary organs (3 males and 5 females) and 8 (5 males and 3 females) various There is some doubt whether the brisk rise in recent years of recorded cancer of the lung can be attributed entirely to better diagnosis or is partly due to highway conditions (tar-spraying and exhaust fumes)

Dr G B Murray, records a substantial rise in notified tuberculosis in 1939 over that of recent years 53 pulmonary cases, which is about 30% above the expected number, and 17 other cases—nearly 3 times the number reported in any of the previous five years, of the new cases 32 were transfers from other districts There were 19 deaths from tuberculosis

From the School Reports

LEICESTER

Dr E K Macdonald's school report has a bearing on the complicated question of nutrition In classifying about 11 000 children into the four grades of nutrition, he found 82 obese children whom he placed in a group apart and made the subject of a special inquiry carried out and recorded by Dr K McAlpine Two types of obesity were distinguished—that with and that without definite sex manifestations The number of cases so far scrutinised is too small and the inquiry has not gone far enough for Dr McAlpine's findings to be reckoned as more than suggestive, but if pursued they may throw much light on many obscure points in development Fatlings have always been puzzling, by some observers they are grouped with the "excellent," by others with the "bad", but probably obesity in children is usually, if not always, due to faulty endocrine balance Many observers have noticed that some evacuated children tend to obesity which in incidence suggests the influence of a psychological and not a nutritional factor

Infectious Disease in England and Wales

WEEK ENDED JULY 12

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 scarlet fever 732, whooping-cough, 4840 diphtheria 773, paratyphoid 293, typhoid, 25, measles (excluding rubella) 5368, pneumonia (primary or influenzal), 531, puerperal pyrexia 129, cerebrospinal fever 184, poliomyelitis, 7 polio-encephalitis, 0, encephalitis lethargica 3, dysentery, 68 ophthalmia neonatorum, 99 No case of cholera plague or typhus fever was notified during the week

Of the 293 cases of paratyphoid 63 were reported from the county of Chester (Birkenhead 28 Bebington 16 Wallasey 14) and 146 from Lancaster (Liverpool 79 St Helens 18 Manchester 15 Widnes 4 West Lancs 4) smaller aggregations from Staffs (Stoke 11 Stafford 6) and Northants (Brixton R D 4), remaining cases widely scattered

The number of civilian and service sick in the Infectious Hospitals of the London County Council on July 9 was 1412 including scarlet fever 129 diphtheria 261, measles 158 whooping-cough, 517 enteritis 16 chicken pox 47 erysipelas 43 mumps 8 poliomyelitis 1 dysentery 1 cerebrospinal fever 37 puerperal sepsis 8 enteric fevers 17 german measles 6 other diseases (non infectious) 82 not yet diagnosed 81

Deaths —In 126 great towns there were 3 (0) deaths from enteric fever 3 (1) from scarlet fever 26 (4) from whooping-cough, 8 (0) from measles, 21 (0) from diphtheria, 41 (3) from diarrhœa and enteritis under 2 years and 6 (1) from influenza The figures in parentheses are those for London itself

Liverpool Manchester and Nottingham each reported a fatal case of enteric fever There were also 4 deaths from diphtheria at Liverpool

The number of stillbirths notified during the week was 183 (corresponding to a rate of 36 per thousand total births) including 13 in London under the transverse metatarsal arch and the toes may, or may not, need a very thin wedge Into the compartment opening along the inner edge, one, two or three leather wedges are inserted to obtain the greatest possible degree of comfort I much prefer these separate leather wedges to one thick wedge of moulded rubber As a precaution the supports were put in the shoes for both feet, and on leaving the shop the patient was able to walk in comfort for the first time in 18 months All sciatic pains disappeared soon afterwards The supports were used for eight years as there was a tendency to recurrence of sciatica when they were left out of the shoes while engaged in strenuous housework They have not been needed during the past year

CASE 2 —In 1937 a sister of this patient had an attack of subacute sciatica which did not yield to medicinal treatment as quickly as desired She then obtained instep supports similar to her sister's The pain quickly subsided, and she left off using the supports after six weeks There has been no return of pain

CASE 3 —A man of about 55 had to give up working as a village postman owing to very severe " sciatica " After treatment in bed for some weeks, at home and in hospital, he attended the outpatient department for about a year He was then told that nothing more could be done to relieve the pain He was still in misery every time he put his foot to the ground His son heard of the benefit derived by the first patient from instep arch supports and got a similar pair His father put them in his boots on a Saturday afternoon and promptly went to see a cricket match He announced, on returning home, that he had had no pain, nor did the sciatica return subsequently

Haynford, nr Norwich ALLAN EDWARD MAHOOD

DI-IODOTYROSINE IN TOXIC GOITRE

SIR,—Mr Wass underestimates the material which exists in this country for the study of thyrotoxicosis If he had referred to the synopsis of three lectures on Toxic Goitre which I delivered in May, 1939, at the British Postgraduate Medical School (*Brit med J* 1939, 2, 436) he would have found that I had used di-iodotyrosine as suggested by Harington in over 600 cases This was given in the form of tablets prepared by Messrs British Drug Houses, the dose employed being usually 2 tablets thrice daily—equivalent approximately to 40 minims of Lugol's solution in 24 hours Since 1938 we have added considerably to the series treated in this way in my clinic, though we do not now employ di-iodotyrosine as a routine for reasons which seem to us cogent—viz, it is relatively expensive and it is no more efficient than is Lugol's solution, though its portability makes it a convenient method of administering iodine But it is, I think, misleading to suggest that di-iodotyrosine has the advantages over iodine which Harington believed on theoretical grounds it might possess, he has never claimed that it exhibits any of these virtues in practice I think, therefore, that Mr Wass is over-optimistic if he hopes to influence favourably with di-iodotyrosine cases which fail to respond to iodine or which have become recalcitrant to its action

Harley Street W 1 CECIL A JOLL

VILLAGE SETTLEMENTS IN WAR TIME

SIR —Dr McDougall is not strictly correct when he says in his letter of July 19 that " the association of a general hospital cheek by jowl with a sanatorium is something new in medical organisation in this country " Although the name of Osler is not primarily associated with the war on tuberculosis, it was ever uppermost in his thoughts On many occasions he stressed the importance of a sanatorium being run in conjunction with a general hospital As a tribute to this ideal, the Osler Pavilion, which is the sanatorium for Oxford and district and at the same time a unit of the Radcliffe Infirmary, was opened in 1926 by Mr Neville Chamberlain, then Minister of Health This association has undoubted advantages—the patients are within easy reach of any type of consultant, are near their relatives, and yet have all the benefits of a sanatorium No less is this so from the teaching point of view—the students have ready access, and pulmonary cases can be and are used for final examinations Gone are the days when it took most of an afternoon to complete the journey to and from the sanatorium That such a scheme can work is shown by the fact that the number of beds at the Osler Pavilion has more than doubled since 1926 The i portant factor for continued success is the absence dual authorities In the presence of the latter t scheme will break down sooner or later

Oxford JOHN GRIEVE

POSITIVE SYPHILITIC TESTS IN HEALTH PEOPLE

SIR,—The question whether positive syphilis tests m occur in non-syphilitic people, as discussed in y *annotation of May 10 (p 606), requires careful conside* tion If care is taken to use suitable antigens and technique adapted to them, false positive reactions be very exceptional, even in blood from patients suffe from a variety of diseases other than syphilis or fr pregnant women Great progress has been made dur the last decades, but the aim has often been to incre the sensitivity of tests and the necessary specificity sometimes been insufficiently considered In c giving false positive results it is general experience t only one or some tests give positive reactions while oth do not It is often advisable, therefore, not to rely single test The more tests that are performed and *more they agree the more certainly is the result diagno* of syphilis This remains true in spite of improvem in technique and reliability of the tests

False positive results are due to an increased " labil of the serum proteins, and are not true antigen-antib reactions This lability is nearly always sufficie reduced by heating the serum to 55° C or, in s flocculation (clarification) tests by using higher concentrations Since non-specific reactivity is v exceptional even in pregnancy or diseases other *t* syphilis, false positive results in really health*y peo* must be rare indeed The fact that anima*l sera oft* react positively with antigens adapted for the examin tion of human serum must not be taken to imply tha the serum of healthy people sometimes gives positiv reactions The non-specific reactivity of the antige depends on the colloidal structure of the serum, and th structure differs in various animals from the structure man Thus antigens and methods suitable for th serodiagnosis of human syphilis cannot be used succes fully for the examination of syphilitic rabbits, for tha specially prepared antigens are needed with a lowe content of cholesterol It is a lucky chance that huma serum has a relatively high degree of stability Eagle report (*Amer J Syph* January, 1941, p 7) on attempt to distinguish " biologic false positive " reactio from cases of latent syphilis is not available to me present, but I should like to mention a method elaborate in my former department by Witebsky (*Z ImmunFors* 1933, 80, 323) by which it is possible, when th serum originates from a syphilitic patient, to recov the antibodies from the flocculates by elution at 55° and thus to differentiate syphilitic reactions from fal positive ones According to Bier and Trapp (*J Immun* 1941, 40, 465) this method may be improved by usi 10% sodium chloride solution instead of 0 9% saline f dissociation This procedure corresponds to that u by Heidelberger (*J exp Med* 1936, 64, 161) for th dissociation of complexes of pneumococcal carb hydrates and their antibodies

Trinity College, Dublin H SACH

SAMPLE OF PUBLIC OPINION

SIR,—In the large number of bodies that are beginni to occupy themselves in medical planning, little oppo tunity has so far been given for the general public voice its views When the claims and counter clai for a state salaried service versus private practice a being put forward by the profession, these usually inclu the profession's own interpretation of what the pub would like It is to be hoped that medical planne will now pay attention to the results of the Gallup surv you published on July 12 (p 59) Asked to choo between (*a*) all doctors and hospitals under state contr (*b*) extension of the panel system to include everybod and (*c*) having a private doctor, the answers from cross-section of the population were 55% for (*a*), 30 for (*b*), and 15% for (*c*) In other words, more th half the population surveyed was in favour of state co trol and a minority for extension of the panel or f simple private practice When the group was brok

RICHARD FOWLER WARD

M B LOND , F.R C S.E , MAJOR, R.A M C

THE death of Major Richard Ward from enemy tion was reported in an Army casualty list on June 11. was born in 1902, the son of Dr Frank Fowler Ward Ipswich He qualified M R C S from the London ospital in 1926 and took his M B Lond the following year After serving as casualty officer and house-surgeon at the East Suffolk Hospital and as senior house-surgeon at the Derbyshire Royal Infirmary, he joined his father in practice in Ipswich and helped him unofficially at the East Suffolk Hospital where Dr Fowler Ward had charge of the V.D and urogenital clinics During this period Richard went regularly to London where he did post-graduate work at St Peter's Hospital with a view to specialising in urogenital surgery On his father's retirement he succeeded him in his ppointments at the East Suffolk He quickly gained r himself, among his colleagues, a reputation as a agnostician and operator, and a member of the honorary staff has written "Ward's work in his specialty was f a high order and he was developing the same proficiency in general surgery A loyal and pleasant colleague is outstanding qualities to my mind were an intellectual sincerity which made him speak his mind without fear or favour, and a deep devotion to duty" On the reorganisation of the medical staff of the hospital some two years ago he gave up general practice and was elected an assistant general surgeon

Since 1929 Ward had been battalion medical officer of the 4th Suffolks and shortly after the outbreak of war ne was mobilised and went to France with a general nospital returning from Boulogne last summer with his unit He was a member of the town council at the time of his death

He leaves a widow and two young children

Scottish Conjoint Board

The following have passed the final examination and on July 18 were admitted licentiates of the Royal Colleges of Physicians and Surgeons of Edinburgh, and of the Royal Faculty of Physicians and Surgeons of Glasgow —

N V Appavoo, H K Banda F H Batchellor, S J Blau A H Brambir, William Brown, Mortimer Burdman, David Davidson, W J Dempster, H H Feldman, W J E Fernando, John Fitzsimons, Samuel Gelband E G Gordon H P Hall, H V Hankins, A S B Hebron, M H Hurwitz, James Ireland, Louis Kaywin, Herman Laret, Morris Links, Emanuel Lipschik Mary K McCabe, Alistair McCall, Thomas McMurray, J C MacWilliam, Irving Markowitz, Herbert Pearl, J M Stewart and L J Swirsky

E Edmund Nobel, M.D Vienna, was also admitted licentiate

Royal College of Nursing

The Minister of Health has informed the college that he contemplates setting up machinery for the consideration of nurses' salaries, and that nurses, hospitals and local authorities will be consulted before he comes to any decision on the matter It is understood that he has in mind a modified form of Burnham scale on the lines suggested by the interdepartmental committee The college, however, maintains that machinery dealing only with the salaries of nurses would be inadequate

Specialists for the R A M C

The Central Medical War Committee is asked from time to time to nominate specialists as lieut colonels in charge of medical or surgical divisions Any specialist in medicine or surgery who wishes to have his name considered for a post of this kind should communicate at once with the secretary of the committee, B M A House, Tavistock Square, London, W C 1

Service Award

The D S O has been awarded to Major F McL Richardson, M.D Edin , R A M C , for gallant and distinguished services in the Middle East

Prisoners of War

In a recent casualty list the following R A M C officers were posted as prisoners of war W. S /Captain H A Barker, M B , Captain A R Darlow, M R C S , Lieutenant J A S Mulligan, M B Belf

National Council for Mental Hygiene

The council is holding a public meeting at 26 Portland Place, London, W 1, on Thursday, July 31, at 5 P M , when Mr Kenneth Walker will speak on the need for a positive philosophy of life

Extra Cheese for Vegetarian Diabetics

On the recommendation of the food rationing (special diets) advisory committee of the Medical Research Council vegetarian diabetics are to receive an extra weekly allowance of 8 oz of cheese in addition to the special ration of 8 oz allocated to vegetarians

◆

Caldecote Hall, Nuneaton, which was taken over by the Ministry of Health last year and later relinquished, has now resumed its normal work of treating neurasthenia and addictions

The Dr Jessie Macgregor prize for 1938–41 has been awarded to Dr Agnes Macgregor for her work on pneumonia in the newborn

Obituary

JOHN DOUGLAS STANLEY

M D EDIN AND BIRM , F R C P

Dr Douglas Stanley, emeritus professor of pharmacology and therapeutics in the University of Birmingham, died at his home at Feckenham on July 5 He was a sound physician and an inspiring bedside teacher, who relied rather upon his own wide clinical experience than upon the written words of the textbooks Sparing of words, he had a dry incisive wit which drove home with emphasis his points and made his lectures memorable

Stanley came of an Ulster family, but began his education abroad, for his father was for some time chaplain at Antwerp, later settling as vicar at Oulton in Norfolk After qualifying in medicine at Edinburgh in 1889, and holding resident appointments at the Royal Infirmary, he completed his studies at the London Hospital and at Lille where he was for a time interne at the hospital In 1893 he went to Birmingham as resident pathologist at the General Hospital and demonstrator in morbid anatomy at the University, and all his life his medicine was founded on a close study of these subjects Some three years later he joined the honorary staff at the Queen's Hospital and the Children's Hospital, and became university lecturer in clinical medicine On the death of Arthur Foxwell he was appointed to the chair of pharmacology and therapeutics He was for some years editor of the *Birmingham Medical Review* and many of his papers there reflect his interest in the diagnosis of diseases of the lung "D S," as he was affectionately called by all, carried his kindness and practical sense into his life outside medicine His old patients and students knew him as a friend and after he retired from his hospitals he continued to serve them well as a member of their boards of management The interests of the Hallam Hospital, West Bromwich, were very near to him and he continued to act as its consulting physician until his death

Stanley retained throughout his life his love of French literature He was a man of wide interests and varied hobbies, amongst which perhaps the chief was the collection of old furniture of which he had a sound knowledge aided by a fine practical craftsmanship in cabinet-making and woodwork On his retirement into the country he parted with a portion of his collection in a sale which attracted considerable attention amongst connoisseurs His Irish glass, china and a selection of illuminated MSS attested his judgment in these antiquarian directions

ROGER NEVILLE GOODMAN

B SC LOND , M D CAMB , D P H

Dr R N Goodman, who died at Oxford on July 9 after an operation, was for 42 years a general practitioner in Kingston-on-Thames, to the freedom of which royal borough he was admitted in 1929 For the last nine years he had been living in retirement at Great Kimble, near Aylesbury

Lafayette

Roger Goodman was born in 1863, the son of Neville Goodman and Maria Cunliffe His forbears were Nonconformist millers and farmers of the Cambridge marches In his youth he sailed with his father round the world and up the Amazon collecting specimens After taking a London science degree he went to Cambridge where he was a scholar of St John's and took the first place in the natural sciences tripos but abandoned an academic career on the death of his father Going on to the London Hospital he qualified in 1887 and held house appointments there and at Brompton In 1890 he took over the practice of E M Shirtliff in Kingston, at first in partnership with A M Daldy, later with J G Owen, E J Woolley and H R Davies, a combination which represented four different London hospitals Almost from the start he was associated with local education, he was a member of the borough and county education committees and on the governing body of the Tiffin School and of the Grammar School, founded in 1305 by Edward Lovekyn whose chantry he was helpful in preserving, obtaining for both the playing fields they needed During the last war he acted as hon anæsthetist to the Epsom War Hospital and later was president of the Surrey branch of the B M A

"To an undergraduate visiting Dr Goodman's hom for the first time twenty years ago," writes T F, " was a little alarming After dinner, at which he nothing but milk pudding, we would sit in his consul room, surrounded by piles of new books I conf that I wanted to be a writer 'But hadn't you be *know* about something before you write?' he ask And when he saw my drawings he remarked that seemed to have drawn first and decided on the subject a wards Such forthright comment cannot always ha pleased patients, colleagues and fellow-townsmen, all were wise to profit by his intelligence and knowle He was serious-minded he did not need the flippa or the sentiment that others use to bypass facts purpose, indeed, was never escape he was honest, feet were squarely on the ground, and the patient was safe in his hands as anyone can hope to be To th who recognised a brain and character far above t average of the profession it seemed that he should ha had more important work to do, but perhaps his wo was as important as any "

At the age of 70 Dr Goodman retired to a house at t foot of the Chilterns, retaining and refreshing tastes th made retirement a happy change of occupations Here h was the shrewd and friendly neighbour, the observer of rar plants in the hedgerows and of the migrating of toads and glow-worms, the student of social and economic movements, and when the crisis came it found him dropping naturally into responsible offices He became a member of the county food control, he was responsible for keeping the register for the medical war committee, and he was the warden to whom everyone turned for help He even started growing belladonna in his field In his reply to those who conferred on him the civic freedom ten years earlier he suggested as his epitaph "He did not know—but he was willing to learn" And it was given to him in large measure to learn to know his fellow men, so that his life was increasingly of service to them

Dr Goodman was twice married, first to Louise Harvey Marriott, matron of Surbiton cottage hospital, who died in 1931, and then to Emily Green Horner, who survives him Dr Neville Marriott Goodman, only child of the former marriage, is a deputy senior medical officer of the Ministry of Health

CHRISTOPHER ROWLAND ALDERSON

M C , M R C S , MAJOR, R A M C

Dr. C R Alderson died in a prison camp on March 20 Born in Bradford in 1893 he joined the Liverpool Scottish in 1913, transferring to the Royal Engineers two years later, and in 1916 he was awarded the military medal He received a commission in 1917 and after the Armistice he saw further service in North Russia and was awarded the military cross After demobilisation in 1920 he studied medicine at University College Hospital, qualifying in 1925 He held house-appointments at the Seamen's Hospital, Greenwich, and the Prince of Wales' Hospital, Tottenham, before he settled down in practice at Eastbourne, also acting as assistant anæsthetist to the Ear, Nose and Throat Hospital there He was recommissioned as a major in the R A M C (T.A) in April, 1939, and was reported missing on June 19 of the following year

---

Surgeon Lieutenant D A Prothero, whose death is announced, qualified in 1935 and took the diploma in anæsthetics of the Royal Colleges two years later Just before the outbreak of war he applied for a short-service commission in the Royal Navy A shipmate who served with him for over a year until the time of his death writes

"I had many opportunities of appreciating David Prothero's skill and clinical acumen and the abundant good nature which endeared him to us all His postgraduate work had given him a firm grasp on his work, and we came to rely upon his abilities"

SOME NUTRITIONAL DEFICIENCIES IN MAN

L S P DAVIDSON
B.A CAMB, M D EDIN, F R C P
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF EDINBURGH

DIETARY deficiency may result directly from an insufficient intake of the necessary food factors, or indirectly from failure in their absorption or because of enhanced demands conditioned by increased metabolic requirements The great majority of clinical syndromes due to dietary deficiency result from an inadequate intake or faulty absorption of vitamins or minerals No clear-cut symptoms develop from insufficiency of carbohydrate or fat other than loss of weight and energy due to a low calorie intake If the protein of the diet is excessively low over a long period, œdema occurs, wounds heal very slowly and imperfectly, and a marked wasting of muscles develops, as a result of the hypoproteinæmia

In normal times fully developed syndromes such as beriberi, scurvy, pellagra and rickets are now uncommon in civilised countries The only exception to this rule is anæmia due to iron deficiency which I have own to be present in at least 50% of women and fants belonging to the poorer classes Minor degrees deficiency in vitamins and minerals are however, ommon The clinical manifestations of such subinical states are somewhat vague, the patient usually omplaining of general ill health loss of appetite and ergy, and sometimes an increased tendency to infecons In children there may be in addition a failure maintain a satisfactory weight and rate of growth nd a proper development of the bony skeleton and eeth The conception that such states of vague ill ealth are due to deficiencies of vital food factors is ased on special chemical methods of assay of the blood nd urine and on the clinical benefits which occur when e dietary deficiency is corrected In some cases of etary deficiencies it is extremely *difficult* to apportion he various manifestations present to a lack of individual od factors Thus, fatigue unduly easily produced and ss of appetite are apparently the earliest symptoms ertaining to deficiency of both vitamins B_1 and C he development of perfect teeth and the prevention of ental caries is dependent on an intake of adequate mounts of vitamins A C and D as well as of calcium ollicular hyperkeratosis is claimed to be a dermal hange induced by deficiency of vitamins A, C and the complex

It is a widely accepted dictum that when a person iffers from malnutrition owing to dietary deficiency, the eficiency is seldom single Even if one clinical syndrome ominates the picture multiple deficiencies are generally resent, although to a less degree This dictum should pply equally to deficiency states conditioned directly by he ingestion of an insufficient or badly balanced diet or directly by a failure in digestion and absorption Its cceptance is a wise procedure for it necessitates in every se of deficiency disease the most careful consideration f the dietary history and a full examination of the linical state in general and of the gastro-intestinal tract n particular Finally it postulates the need for supplyng a diet adequate in all essential nutritional principles his aspect was clearly demonstrated by a nutritional xperiment carried out under my direction some years go Several hundred children belonging to the poorest lasses, whose parents were mainly unemployed, were iven a daily supplement of vitamins A and D in a apsule, while an equal number of children from the ame school were given a similar capsule containing rachis oil At the end of six months no significant ifference was found in the two groups in regard to gain n height or weight or resistance to infection Since it as been clearly proved that a supplement of a pint of ilk daily will produce a remarkable improvement in utrition of children who are taking a poor diet, it must e assumed that the experiment failed to achieve this esult because only two out of the four vitamins which were deficient in the diet were supplied while the important deficiencies of iron and calcium and first-class *protein so necessary for growth were not corrected* The conclusions reached were that a deficient diet should be corrected by the giving of adequate quantities of the natural foods and that supplements of vitamins should be employed only for the treatment of established states of deficiency disease Nevertheless, I have often had patients under my care with a fully developed deficiency disease clearly conditioned by *an insufficiency of one* particular food factor with no clinical evidence of other deficiency syndromes, in spite of the diet being grossly defective in many respects or intestinal absorption being gravely impaired

The *object of the present communication* is to illustrate this aspect with the case-histories of nine patients suffering from a variety of deficiency states, all of whom I investigated during the spring of 1941 and demonstrated at a clinical meeting at the Western General Hospital, Edinburgh The nine cases are divided into three groups group 1, three cases of manifest scurvy, group 2, three cases of severe nutritional iron-deficiency anæmia in children, group 3, three cases of nutritional deficiency due to a failure in absorption of food factors from the small intestine, secondary to surgical interference

GROUP 1 · MANIFEST SCURVY

The three patients were elderly men aged 64 68 and 74, who for various reasons were living alone and undertaking their own catering and cooking All had small incomes and admitted that with the increased cost of living they had been forced to curtail their expenditure *on food For at least six months they had made no attempt to do any cooking and lived on* a diet of white bread, margarine, jam and tea supplemented on occasions by bought cooked meat sausage rolls or mutton pies No fresh fruits or green vegetables had been eaten for at least six months, potatoes were very seldom eaten, while *milk* was purchased in quantities sufficient only for tea The clinical manifestations of all three patients were the same—progressive weakness and loss of appetite and the development shortly before admission to hospital of pains in the limbs due to widespread bruising and *hæmorrhage into the muscles* The capillary-fragility tests were positive Sponginess and bleeding from the gums was absent in all three cases Two of the patients were edentulous and one had very septic teeth A considerable degree of anæmia was present the hæmoglobin percentages being respectively 58, 26 and 55 In two of the cases treatment with ascorbic acid produced a reticulocyte crisis followed by a *rise in the red cells* and hæmoglobin In one case no response was obtained until supplementary iron treatment was given, when a satisfactory improvement quickly resulted This patient had a hypochromic blood picture and had been losing blood from hæmorrhoids for a *long time* Accordingly it is suggested that ascorbic acid will only produce its specific hæmatological effects if the material required for the formation of erythrocytes and hæmoglobin is available in adequate amounts None of the three patients had free acid in the gastric juice, and this finding on theoretical grounds at least, suggests the possibility of impaired digestion and absorption of vital food factors It is therefore, of interest to note that, despite the achlorhydria and the ingestion of a grossly deficient diet none of the patients showed any clinical symptoms or signs to indicate a deficiency of vitamins A B_1 B_2 complex or D, with the exception that one patient had a smooth atrophic tongue which might be ascribed to deficiency of the vitamin-B_2 complex

The administration of a well-balanced *diet* with large quantities of ascorbic acid rapidly caused a complete disappearance of all the clinical manifestations of scurvy and the restoration of normal health

GROUP 2 IRON-DEFICIENCY ANÆMIA IN CHILDREN

The three children were aged 5, 6 and 8 years and came from one family They had been shockingly neglected by an alcoholic mother who had been drinking heavily for at least two years They were admitted to hospital *in a dirty*, verminous condition The striking feature

Notes, Comments and Abstracts

HEALTH OF PALESTINE

THE report for 1939 of the Department of Health of Palestine is more comprehensive than might be expected in these disturbed times Its chief interest lies in the comparison of the health of the three chief races Jews, Arabs and Christians, for the health services are in essence similar for all The results, however, do not tell us of differences in health due to true racial causes (though they appear to do so), but of the uses made of the health services and of how far this use is influenced by prejudice, energy and obstruction The cost of the services was 3 9% of the total estimated government expenditure Unfortunately 1939 was much disturbed by political strife which prevented developments of health work, but in spite of this the health of the population was remarkably good and there were no important epidemics The recorded incidence of infectious diseases was the lowest for many years, and the death-rate from them half that of 1931 The total population was 1,501,698—roughly 60% Moslems, 30% Jews and 10% Christians and others The birth-rate was twice as high in the Moslems (46 4) as in the Jews (23 0) Both rates are falling, that of the Jews more rapidly than that of the Moslems The death-rate of the Moslems is much more than double that of the Jews In 1939 the respective rates were 17 4 and 7 6 Here again both rates are falling, but that of the Moslems more rapidly Infantile mortality was 121 5 per 1000 live births among the Moslems and 54 among the Jews, in Christians the rate was 101 These rates are the lowest ever recorded and show a sharp decline from previous years

In the 29 main towns there were 7799 deaths, of which all but 671 could be classified There were 66 suicides, 344 homicides and 290 deaths from other violence The numbers of homicides and suicides are exceptional before 1938, when troubles became serious, the rates were comparatively low Diarrhœa caused 1336 and pneumonia 1258 deaths, then, in order, come heart diseases 617, cancer 364, cerebral hæmorrhage 311, and nephritis 276 The reported incidence of malaria was 3394 cases with 15 deaths, of typhoid 1235 cases with 134 deaths, of paratyphoid 175 cases with 2 deaths Tuberculosis gave 461 cases with 207 deaths, which seems hardly credible In this connexion we are told that the population in general has not been exposed to tuberculosis as much as most civilised communities, and that a progressive increase in morbidity and mortality may be anticipated unless proper prevention and control measures are instituted It is satisfactory to note that there has been no increase in tuberculosis in the past ten years A survey carried out in 1934 included Mantoux testing of 18,737 Arab children, and 15% gave positive responses A more recent test returned 13 6% positive Ophthalmias are a formidable problem in Palestine, for trachoma is widespread, epidemics of acute conjunctivitis (Koch-Weeks) are perennial and gonorrhœal ophthalmia apparently common In a population of 304,532, blindness in one eye was found in 8534 (present in 47 from birth) and total blindness in 3462 (present in 78 from birth)

MEDICINE UNDER TOTALITARIANISM

MOST people now realise the unhappy position of the arts in the countries where, under a totalitarian regime, all human enterprise must be harnessed to the cart of the state (or dragged unwillingly at the cart's tail) In Italy, at any rate, medicine is in the same uncomfortable situation, judging by a contribution to *L'attualita medica* (1940, 5, 198) which has somehow succeeded in reaching this country In this article, which is called "How to spread Italian culture," L Verney remarks in language recalling the old-fashioned religious tract that "we must strain every nerve to make Italy a cultural lighthouse, diffusing abroad the spirit of latinity", and this "not for sentimental reasons, but because of the resulting repercussions in the political and economic spheres" He complains that there is a lamentable neglect in foreign countries of Italy's contribution to medical knowledge, as he looks through the review columns of foreign periodicals he scarcely ever finds a review of an Italian book "It seems," he argues, "that our pu lishers do not think of sending books abroad for review otherwise this silence is inexplicable" There may, fact, be another explanation Other measures a advocated, such as the establishment in foreign countr of depots for the sale of Italian books and periodical translation of Italian literature into other language exchange of research workers and students with ot countries "Cultural propaganda must reach the le of the new Italy It must become worthy of our r destiny" Verney seems to feel no doubt that t offspring of the marriage between medicine and the st will be received with enthusiasm by the inhabitants less enlightened countries The war rather restricts t range of the activities he advocates, but his plans presumably part of the New Order which is to issue fr a German-Italian victory

STILL'S VERSES

THE small volume "Childhood and other Poem (John Murray, pp 152, 5*s*), by the late Sir Freder Still, recalls the old Greek epigram, so brilliantly tra lated by Cory, another lover of children

> They told me, Heraclitus, they told me you were dead,
>
> Still are thy pleasant voices, thy nightingales, awake
> For Death, he taketh all away, but them he cannot ta

"Pleasant voices" almost exactly describes the charac of these verses, for they are rather the exercises of accomplished and scholarly mind than the inspi effusions of a poet They will be treasured by *all* w knew their author, but can scarcely make a wider *app* to the lover of poetry, for with all their *felicity* language, and polished and careful art, they *lack the fi* and ardour of original thought

MEADOWS S P, M D Lond F R C P temp asst physician Hereford County Hospital

*__PARKER J N__, M B Manc D P H deputy medical sup intendent at Baguley Sanatorium nr Manchester

* Subject to confirmation

DISCUSSION

The nine cases reported clearly indicate how, in the presence of a diet apparently grossly deficient in many factors, a single clear-cut deficiency syndrome may dominate the clinical picture Moreover, the dominant syndrome may be that of a particular vitamin or mineral deficiency in one patient and a different picture may be present in another ingesting an apparently similarly deficient diet In the group of patients with manifest scurvy, it would be easy to argue that the dominant picture was scurvy because of the widely accepted view that vitamin C is one of the vitamins that man is unable to synthesise or store in the body for any length of time But if this simple explanation is correct, it would be necessary to explain why the three young children with severe iron-deficiency anæmia, whose requirements of vitamin C should be high in view of the demands of growth, showed not a single sign of the scorbutic syndrome A study of the three cases of indirect dietary deficiency resulting from diarrhœa, small intestinal hurry and reduction of available absorptive areas in the small intestine showed that each developed entirely different clinical pictures Why did the patient with the gastro-jejuno-colic fistula who had the most severe and the most prolonged diarrhœa show no obvious signs of vitamin or mineral deficiency and only loss of weight ? Why did the boy of 19 develop pernicious anæmia with no signs of neuritis or dermatitis, while the woman of 60 developed an iron-deficiency anæmia with typical pellagrous skin and tongue lesions ? At present no answer can be given to these and other questions, but it is apparent that there still exist many gaps in our knowledge of deficiency diseases in man which can be bridged only by careful study of the factors which affect the absorption, synthesis, storage and utilisation of vital constituents of food Finally, the accepted standards of minimal amounts of vitamins and minerals needed to prevent the appearance of clinical symptoms and signs obviously requires reconsideration

SUMMARY

A fully developed deficiency disease due to lack of one particular food factor may be present although the diet is defective in many respects or intestinal absorption is gravely impaired

This is illustrated by three cases of manifest scurvy in elderly men, three of severe nutritional iron-deficiency anæmia in children, and three of nutritional deficiency due to failure of intestinal absorption after operation

The different clinical pictures seen in these cases cannot be explained on our present knowledge of the absorption, synthesis, storage and utilisation of foodstuffs, and further detailed studies of the factors influencing these are needed

I wish to record my thanks to Professor McNeil and Professor Learmonth for allowing me to investigate the patients in group 2 and group 3

REDUCTION OF DUST-BORNE BACTERIA BY OILING FLOORS

JOHN C THOMAS, M R C S

MAJOR, R A M C , OFFICER IN CHARGE OF A MILITARY LABORATORY

IT is becoming increasingly recognised that floor dust plays an important part in ward cross-infection, and it is reasonable to suppose that it may be equally important when it accumulates in places occupied by large numbers of people—for example, in air-raid shelters This hazard is undoubtedly enhanced by the inadequate ventilation associated with the blackout

Most dust organisms are innocent saprophytes, but the presence of pathogens in many circumstances is now well established Owing to the ease with which they are recognised, most of the work done on dust pathogens has been concerned with hæmolytic streptococci They have been recovered from the dust of burn wards and puerperal and scarlet-fever wards (Cruickshank 1935, White 1936, Allison and Brown 1937), and under experimental conditions van den Ende, Lush and Edward (1940) have shown that a group-B (Aronson) streptococcus retains its virulence in dust for at least 4 weeks I have confirmed this with group-A strains, and have repeatedly grown *Streptococcus pyogenes* from the air, bedclothes and dust of wards in which there have been outbreaks of follicular tonsillitis Recently, during a single sweeping of such a ward and its annexes, 102,000,000 of these organisms were recovered from the dust (Thomas 1941) Other pathogens known to persist in dust are *Corynebacterium diphtheriæ*, the pneumococcus and the tubercle bacillus, and a number of viruses probably retain their virulence there also

This paper describes experiments made in hospital with spindle oil,* which was shown by van den Ende and his colleagues to be highly effective in reducing aerial contamination from dust It is interesting to note that it has taken more than 30 years and the present conditions to demonstrate the importance of an oil which was the main constituent of 31 dust-laying oils investigated by Heise in 1909

Most of the experiments were made in the hospital canteen Other experiments were made in a ward during an outbreak of acute streptococcal tonsillitis (mixed types 3 and 6), during which large numbers of β-hæmolytic streptococci were recovered from the air, while a smaller series of tests was made by oiling the operating-theatres corridor The experiments were made in collaboration with the team of workers at the National Institute for Medical Research, as part of a larger investigation into the problems of air-borne infection (Andrewes et al 1940)

METHODS OF AIR SAMPLING

Air counts were made, usually on 10 c ft volumes, on 4 in plates of a 1/500,000 gentian violet blood-agar (prepared by adding 2 ml of 1 in 10,000 aqueous gentian violet solution to 100 ml of melted nutrient agar just before adding 10% horse blood), which Garrod (1933) showed to be a selective medium for certain aerial pathogens † The plates were incubated aerobically for 18–24 hours and the colonies counted as total organisms , total α-hæmolytic organisms , and β-hæmolytic streptococci The last were picked off into serum broth and tested after 15 hours for soluble hæmolysin production , positive strains were examined serologically by the late Dr F Griffith, of the Research Institute for Streptococcal Infections, Hammersmith A few plates were incubated anaerobically and yielded almost pure cultures of streptococci (Fuller and Maxted 1939) In all, 1026 plates were exposed, 703 in the canteen and 323 in the wards

The medium was tested before use by exposing a number of plates simultaneously with others of plain blood-agar both in a ward with a high streptococcus/saprophyte ratio, and in the canteen where the ratio is reversed In each case Garrod's findings were confirmed (table I) There is a considerable reduction in the total count (about 95%), due almost entirely to a reduction in saprophytes, the streptococci being almost unaffected The gentian violet blood agar medium inhibits the growth of *Bacillus subtilis* and moulds, and yields plates entirely free from spreaders In the same table are given comparative figures for two other experiments, A and B (not directly related to spindle oil tests), in each of which the reduction ratio is of the same order That it is lower in experiment A than in experiment B is directly referable to the fact that the dust saprophytes had already been artificially reduced in A, while in B they were allowed to accumulate

A number of methods are available for enumerating bacteria in air, none of which is perfect The simplest is to expose petri dishes and allow organisms to precipitate on them for a given time Counts by this method, however, vary considerably with experimental conditions of their appearance was intense pallor, which was due to severe hypochromic microcytic anæmia The hæmoglobin levels on admission were 17%, 23% and 45% The youngest child, with the lowest hæmoglobin, showed much œdema, especially of the lower limbs, which was thought to be due partly to the severe anæmia and partly to hypoproteinæmia The children's intelligence was satisfactory and no evidence of organic disease in any organ was found A careful investigation of their diet showed that for at least a year before admission to hospital no fresh fruit, green vegetables or eggs had been consumed One pint of fresh milk for the whole family was purchased on rare occasions Their meals consisted essentially of white bread, margarine, jam and tea, sweetened with condensed milk Sometimes, when their father found time to cook, they were given a soup of some kind, or more rarely a stew Fried chip potatoes were eaten fairly frequently at tea On occasions a mutton pie or some cooked meat was purchased Cod-liver oil was never taken

---

* Spindle oil is a crude, heavy petroleum oil, used extensively in the cotton industry as a lubricant The samples used had the following specifications colour, yellow , odour, strong , cloud test at 0° C clear , specific gravity 0 886 kinematic viscosity 53 21 centistokes at 20° C 22 3 centistokes at 37 8° C, Redwood viscosity 201 sec at 70° F 95 sec at 100° F 52 sec at 140° F flash point (Pensky Martin) closed 178° C (352° F) open 187° C (369° F) The oil was supplied by Stemco Ltd under the name Yellow Oil No 2

† A smaller series of experiments suggest that crystal violet and methyl violet 6B exert a similar selectivity in the same concentration

Despite a diet which appeared to be grossly defective in many respects, these growing children were of normal height and weight, showed no undue capillary fragility or other hæmorrhagic features suggestive of scurvy, no clinical or radiological signs of rickets, and no dermal, neural or cardiac changes suggestive of vitamin-B deficiency Gross dental caries was present On a well-balanced diet, with the addition of ferrous sulphate, there was a rapid rise in the hæmoglobin level, and in a few weeks the children were restored to perfect health

GROUP 3 DEFICIENCY DUE TO FAILURE OF ABSORPTION

Case 1 —Female aged 60 The patient was sent to Professor Learmonth because of diarrhœa and frequent vomiting, with a suggested diagnosis of subacute intestinal obstruction Three months previously she had had a gastro-enterostomy performed in London for pyloric obstruction A few days after the operation she started to vomit, but as air-raids were frequent and the patient very nervous the vomiting was attributed to functional causes The patient returned to her home in Scotland, where she ate a diet which became progressively less and less satisfactory both qualitatively and quantitatively She says that this reduction in her diet was made because she was afraid to eat in case pain and vomiting recommenced About one month before I saw her a watery diarrhœa began, the number of motions being as high as 9 daily, incontinence developed and vomiting began again Anorexia was severe, weight was rapidly lost and the tongue became painful, red and fissured Pigmentation of the skin, especially of the parts exposed to sunlight, was noticed, and by the time the patient was admitted to a nursing home, the classical picture of fully developed pellagrous skin lesions was observed The temperature was elevated and the patient was mentally dull A moderate degree of iron deficiency anæmia was present, the blood-count being red cells 3,400,000, Hb 62%, colour-index 0 91, white cells 9800

Recognising the nutritional aspects of the case and suspecting that the gastro intestinal symptoms were not due to intestinal obstruction from adhesions, Professor Learmonth put the patient under my charge She was given large doses of nicotinic acid, yeast and iron by mouth and liver extract by injection Within 48 hours the vomiting and diarrhœa had ceased and appetite had returned Within a week a remarkable improvement was observed in the pigmentation, glossitis and dermatitis, and within six weeks the patient was restored to perfect health and normal weight

Case 2 —Male aged 19 At the age of 16 the patient developed acute appendicitis Perforation occurred, with subsequent peritonitis Appendicectomy with suprapubic drainage was carried out A fæcal fistula developed later, which would not close According to his operation notes, an ileo-transverse colostomy was performed, with exclusion of the distal loop The fistula closed after three months but subsequently recurred At a later date an operation for subacute intestinal obstruction was performed Despite further surgical procedures the fistula never closed, injection of uroselectan through the abdominal sinus indicated that a communication existed between the cæcum and the rectum In addition to the loss of much food residue through the external fistula, vomiting and diarrhœa were constantly present and the boy's condition steadily deteriorated

By the time he was admitted to the wards of the Western General Hospital under the charge of Professor Learmonth he was grossly emaciated and very pale Physical examination revealed no evidence of organic disease in the heart, lungs or abdomen other than the features already recorded His blood-count was red cells 2,500,000, Hb 60%, colour index 1 16, white cells 7000, the blood picture was typical of pernicious anæmia The test meal showed a histamine fast achlorhydria and a sugar-tolerance test showed a flat blood sugar curve characteristic of poor intestinal absorption Despite the long history of anorexia, vomiting, diarrhœa and external loss of intestinal contents no clinical evidence of scurvy, pellagra, neuritis or tetany was found

The patient was given 4 c cm of Campolon by injection and ferrous sulphate tablets by mouth A reticulocyte rise of 14% resulted, but the blood-count remained stationary for twelve days Between the fifth and seventh day, 30,000 units of vitamin B_1 was given by parenteral injection From the twelfth to the twenty-fifth day of treatment, 2 c cm of Anahæmin was given every second day, and thereafter on every third day during the period of this therapeutic investigation The reticulocytes rose to 17% on the ninth day after the commencement of treatment with anahæmin, but the red-cell and hæmoglobin levels remained stationary during the next 18 days He was given 500 mg of ascorbic acid daily concomitantly with the iron, liver extract and vitamin B A third rise of reticulocytes to 11% occurred and the blood-count began to improve, a gain of half a million erythrocytes being made during the next ten days Large daily doses of nicotinic acid were now given but no further improvement in the blood count resulted Finally the protein of the diet was increased to 150 g daily, and the red cells steadily rose to 4,500,000 and the hæmoglobin to 88% in four weeks, with a corresponding improvement in the patient's general health and strength

As the fistula was still discharging Professor Learmonth decided to operate At operation it was found that the loop of small intestine which had previously been anastomosed with the transverse colon was the jejunum and not the ileum The length of small intestine available for absorption was about four feet This was considerably less than indicated in the records of the previous operation Unfortunately the patient only survived the operation for a few days, death being due to peritonitis resulting from leakage at the fifth and last anastomosis performed for the restoration of the continuity of the bowel Histological examination of long strips of the stomach, extending from the fundus to the pylorus, showed the mucosa to be healthy, no evidence of glandular change or muscular atrophy being present

These findings clearly indicate that the blood picture of pernicious anæmia in this patient was not the result of a failure in the production of Castle's intrinsic factor by the stomach but was conditioned by defective absorption It is in this group of the megalocytic anæmias that I have often found the response to parenteral liver therapy unsatisfactory until it is supplemented by ample amounts of vitamins and minerals and in particular by a high protein diet

Case 3 —Male aged 45 Twelve years previous to admission to hospital the patient had a duodenal ulcer which perforated At operation the perforation was closed and the peritoneal cavity drained Recurrent epigastric pain eventually led to a gastro enterostomy being carried out in 1938 Twelve months later the patient began to have a watery diarrhœa, with two to six motions daily In January, 1941, two months before admission to the wards under the charge of Professor Learmonth, a rapid deterioration set in, the patient having as many as 36 stools a day Four stones in weight were lost during this period On physical examination the patient was found to be still fairly well-nourished, the skin being soft and elastic and the weight being approximately 10 st There were no abnormalities of the heart or lungs A mild hypochromic anæmia (Hb 86%) was present A history of tingling and numbness and carpopedal spasm suggestive of tetany was obtained, but the blood calcium was normal A diagnosis of gastro-jejuno colic fistula was made on clinical grounds, and this was confirmed by X rays and subsequently at operation Some ten days after the operation the patient developed a pulmonary infection from which he died At autopsy bronchopneumonia and empyema were found There were no signs of peritonitis Correction of the gastro-jejuno colic fistula had been successfully accomplished

It was remarkable that despite the prolonged and severe diarrhœa and the fact that so much of the absorptive area of the small intestine had been short circuited, the patient showed only a marked loss of weight, and no dermal, glossal, neural or vascular features suggestive of deficiency of any vitamin

DISCUSSION

The nine cases reported clearly indicate how, in the presence of a diet apparently grossly deficient in many factors, a single clear-cut deficiency syndrome may dominate the clinical picture Moreover, the dominant syndrome may be that of a particular vitamin or mineral deficiency in one patient and a different picture may be present in another ingesting an apparently similarly deficient diet In the group of patients with manifest scurvy, it would be easy to argue that the dominant picture was scurvy because of the widely accepted view that vitamin C is one of the vitamins that man is unable to synthesise or store in the body for any length of time But if this simple explanation is correct, it would be necessary to explain why the three young children with severe iron-deficiency anæmia, whose requirements of vitamin C should be high in view of the demands of growth, showed not a single sign of the scorbutic syndrome A study of the three cases of indirect dietary deficiency resulting from diarrhœa, small intestinal hurry and reduction of available absorptive areas in the small intestine showed that each developed entirely different clinical pictures Why did the patient with the gastro-jejuno-colic fistula who had the most severe and the most prolonged diarrhœa show no obvious signs of vitamin or mineral deficiency and only loss of weight? Why did the boy of 19 develop pernicious anæmia with no signs of neuritis or dermatitis, while the woman of 60 developed an iron-deficiency anæmia with typical pellagrous skin and tongue lesions? At present no answer can be given to these and other questions, but it is apparent that there still exist many gaps in our knowledge of deficiency diseases in man which can be bridged only by careful study of the factors which affect the absorption, synthesis, storage and utilisation of vital constituents of food Finally, the accepted standards of minimal amounts of vitamins and minerals needed to prevent the appearance of clinical symptoms and signs obviously requires reconsideration

SUMMARY

A fully developed deficiency disease due to lack of one particular food factor may be present although the diet is defective in many respects or intestinal absorption is gravely impaired

This is illustrated by three cases of manifest scurvy in elderly men, three of severe nutritional iron-deficiency anæmia in children, and three of nutritional deficiency due to failure of intestinal absorption after operation

The different clinical pictures seen in these cases cannot be explained on our present knowledge of the absorption, synthesis, storage and utilisation of foodstuffs, and further detailed studies of the factors influencing these are needed

I wish to record my thanks to Professor McNeil and Professor Learmonth for allowing me to investigate the patients in group 2 and group 3

REDUCTION OF DUST-BORNE BACTERIA BY OILING FLOORS

JOHN C THOMAS, M R C S
MAJOR, R A M C , OFFICER IN CHARGE OF A MILITARY LABORATORY

IT is becoming increasingly recognised that floor dust plays an important part in ward cross-infection, and it is reasonable to suppose that it may be equally important when it accumulates in places occupied by large numbers of people—for example, in air-raid shelters This hazard is undoubtedly enhanced by the inadequate ventilation associated with the blackout

Most dust organisms are innocent saprophytes, but the presence of pathogens in many circumstances is now well established Owing to the ease with which they are recognised, most of the work done on dust pathogens has been concerned with hæmolytic streptococci They have been recovered from the dust of burn wards and puerperal and scarlet-fever wards (Cruickshank 1935, White 1936, Allison and Brown 1937), and under experimental conditions van den Ende, Lush and Edward (1940) have shown that a group-B (Aronson) streptococcus retains its virulence in dust for at least 4 weeks I have confirmed this with group-A strains, and have repeatedly grown *Streptococcus pyogenes* from the air, bedclothes and dust of wards in which there have been outbreaks of follicular tonsillitis Recently, during a single sweeping of such a ward and its annexes, 102,000,000 of these organisms were recovered from the dust (Thomas 1941) Other pathogens known to persist in dust are *Corynebacterium diphtheriæ*, the pneumococcus and the tubercle bacillus, and a number of viruses probably retain their virulence there also

This paper describes experiments made in hospital ith spindle oil,* which was shown by van den Ende nd his colleagues to be highly effective in reducing aerial ontamination from dust It is interesting to note that has taken more than 30 years and the present conditions to demonstrate the importance of an oil which was he main constituent of 31 dust-laying oils investigated y Heise in 1909

Most of the experiments were made in the hospital anteen Other experiments were made in a ward during an outbreak of acute streptococcal tonsillitis (mixed types 3 and 6), during which large numbers of β-hæmolytic streptococci were recovered from the air, while a smaller series of tests was made by oiling the operating-theatres corridor The experiments were made in collaboration with the team of workers at the National Institute for Medical Research, as part of a larger investigation into the problems of air-borne infection (Andrewes et al 1940)

METHODS OF AIR SAMPLING

Air counts were made, usually on 10 c ft volumes, on 4 in plates of a 1/500,000 gentian violet blood-agar (prepared by adding 2 ml of 1 in 10,000 aqueous gentian violet solution to 100 ml of melted nutrient agar just before adding 10% horse blood), which Garrod (1933) showed to be a selective medium for certain aerial pathogens † The plates were incubated aerobically for 18–24 hours and the colonies counted as . total organisms , total α-hæmolytic organisms , and β-hæmolytic streptococci The last were picked off into serum broth and tested after 15 hours for soluble hæmolysin production ; positive strains were examined serologically by the late Dr F Griffith, of the Research Institute for Streptococcal Infections, Hammersmith A few plates were incubated anaerobically and yielded almost pure cultures of streptococci (Fuller and Maxted 1939) In all, 1026 plates were exposed, 703 in the canteen and 323 in the wards

The medium was tested before use by exposing a number of plates simultaneously with others of plain blood agar both in a ward with a high streptococcus/saprophyte ratio, and in the canteen where the ratio is reversed In each case Garrod's findings were confirmed (table I) There is a considerable reduction in the total count (about 95%), due almost entirely to a reduction in saprophytes, the streptococci being almost unaffected The gentian violet blood agar medium inhibits the growth of *Bacillus subtilis* and moulds, and yields plates entirely free from spreaders In the same table are given comparative figures for two other experiments, A and B (not directly related to spindle oil tests), in each of which the reduction ratio is of the same order That it is lower in experiment A than in experiment B is directly referable to the fact that the dust saprophytes had already been artificially reduced in A, while in B they were allowed to accumulate

A number of methods are available for enumerating bacteria in air, none of which is perfect The simplest is to expose petri dishes and allow organisms to precipitate on them for a given time Counts by this method, however, vary considerably with experimental conditions such as bacterial size, air currents, humidity, and size and position of the plates. With simple plates it is common to find an artificially high saprophyte/pathogen ratio (as is to be expected from the relative sizes of the two types); indeed, unless there are a very large number of pathogens in the air none may be grown at all. Wells's air-centrifuge, in which the organisms are deposited on the sides of agar-lined tubes, is a considerable improvement on simply exposed plates for quantitative analysis. But the apparatus is troublesome to use and difficult to procure, and since its sensitivity to spreaders is high, counts are often difficult to make with any accuracy.

---

* Spindle oil is a crude, heavy petroleum oil, used extensively in the cotton industry as a lubricant The samples used had the following specifications colour, yellow , odour, strong cloud test at 0° C clear specific gravity 0 886 kinematic viscosity 53 21 centistokes at 20° C 22 3 centistokes at 37 5° C, Redwood viscosity 201 sec at 70° F 95 sec at 100° F 52 sec at 140° F , flash point (Pensky-Martin) closed 178° C (352° F) open 187° C (369° F) The oil was supplied by Stemco Ltd under the name Yellow Oil No 2

† A smaller series of experiments suggest that crystal violet and methyl violet 6B exert a similar selectivity in the same concentration

Bourdillon, Lidwell and Thomas (1941), by combining the principle of Owen's dust-counter with that of Hollaender and dalla Valle's (1939) apparatus for air counts, have recently produced at Hampstead an efficient piece of apparatus for this purpose which they call the “ slit sampler.” ‡

Essentially it consists of a small, air-tight, metal box in which is a mechanically rotated table for the Petri dish turning at a constant, slow speed (2 revolutions per min.). Air is drawn into the chamber by a power-driven pump, through a radial slit, measuring 1.1 in. by 0.01 in., in the top of the box, the rate of flow being controlled by an adjustable valve in the suction circuit. The actual rate of air-flow over the plate is measured by a simple water manometer calibrated by a flow-meter with a single mark equivalent to a flow of 1 c. ft. per min., at which rate the machines are designed to work. Not all the organisms entering through the slit are retained on the plate; some are inevitably carried over and lost. With a constant rate of air-flow, however, this error, though possibly selective, should be constant and therefore of no significance. The efficiency of our machines was believed to be upwards of 70% for organisms of 2μ or more in size. It fell, however, sharply with smaller organisms, and when tested against a single organism spray of *Strep. salivarius* or *Chromobacterium prodigiosum* was as low as 15–20%. There is not this falling off of efficiency with smaller organisms in the high-plate machines, while their efficiency against larger organisms is of a high degree. In the present spindle oil experiments we are dealing with these larger organisms and aggregates and there is no reason to doubt the efficiency of the apparatus for such a purpose. All my experiments have been made with these machines.

TABLE I—AIR-SAMPLING: COMPARISON OF BLOOD AGAR (BA) AND 1/500,000 GENTIAN VIOLET BLOOD AGAR (GVBA) AS MEDIA FOR AERIAL COUNTS

	Preliminary tests				Subsequent tests (total organisms only)			
	Total organisms		β streptococci		Expt A		Expt B	
	BA	GVBA	BA	GVBA	BA	GVBA	BA	GVBA
Plates exposed	92	92	30	30	62	134	45	124
Total count	12,334	3284	35	305	4827	3096	9854	6904
Vol. of air tested (c. ft.)	212	920	30	300	124	1340	90	1240
Organisms per c. ft.	58.21	3.57	1.17	1.02	38.90	2.31	109.8	5.57
Reduction ratio	16.3/1		1.14/1		16.8/1		19.7/1	

In a preliminary control period the efficiency of the slit sampler (SS) was tested simultaneously against simply exposed (SE) plates (table II). The SS plates recovered nearly six times as many organisms in the same time as the SE plates. The most significant increase, however, is not in the total number of organisms but in the finer, more slowly sedimenting streptococci, of which eleven times as many were recovered. This was strikingly demonstrated on one occasion in the epidemic ward when an SS plate grew 39 β-hæmolytic streptococci compared with a single colony appearing on an SE plate. Again, in a clean surgical ward of another hospital we recovered β-hæmolytic streptococci on 5 out of 8 SS plates, although a continuous series of SE plates over a period of days had failed to demonstrate a single pathogen.

TABLE II—COMPARISON OF SLIT SAMPLER (SS) AND SIMPLY EXPOSED PLATES (SE) (100 PARALLEL PLATES)

Mean colonies per plate	SS	SE	RATIO SS/SE
Total organisms	81.79	14.22	5.75
Total α hæmolytic organisms	44.50	8.91	4.99
β streptococci	1.00	0.09	11.11

The slit sampler, moreover, gives remarkably constant results when sampling a steady atmosphere, and yet by reason of its speed of sampling is sensitive enough to reflect in the plate-count any sudden event which increases the aerial flora. In the same ward consecutive plates yielded 84, 84, 98 and 85 organisms of which 24, 22, 24 and 23 were β-hæmolytic streptococci, while an adjacent ward gave comparably steady counts of 34, 26, 30, 29, 31 and 25 total organisms with 9, 9, 10, 8, 6 and 10 β-hæmolytic streptococci growing on gentian violet blood-agar.

EXPERIMENTS IN THE CANTEEN

The canteen is a large, low room of nearly 35,000 ft. capacity, with doors at either end; it is relatively poorly ventilated in winter owing to the blackout. The floor is of plain, unpolished, oak boards. It is open for twelve hours a day and during these experiments was used by probably 1000 people each day, up to 200 people being present at a time. It contains two full-size billiard tables, a table-tennis table, and many tables and chairs, apart from the serving counters. The actual floor space walked on is therefore much less than the total of 2900 sq. ft., and there is concentrated wear on certain parts. The slit samplers were placed in a constant, central position; the slit entrance was 3 ft. from the floor.

Control experiments.—At the outset the canteen wa swept in a haphazard manner by a number of convalescent patients, who raised a considerable amount o dust. The aerial counts rose from a mean of 0.7 organism per c. ft. before sweeping to 24.1 per c. ft. during the actual sweeping period. The fall in the air count as soon as sweeping was completed was very rapid, and even with peaks of 300 or more organisms per plate, the count fell to normal within 30 min. (fig. 1). This is due to the fact that many of the dust organisms are adherent to minute particles of rapidly sedimenting dust (during sweeping a visible film of dust appears on the plates).

With the introduction of organised sweeping the peak counts were promptly halved, the mean sweeping counts being 10.4 per c. ft. for three consecutive days. During this time the men learned to sweep in the same way each day, so that the subsequent counts should be as nearly comparable as possible. These experiments proved the adage “ too many cooks . . . ” for much more dust was caused by a number of men sweeping than by one going quietly about the job (fig. 2). It was often noticed that subsequent dusting produced an even higher peak than that met with during sweeping. This is because during dusting organisms are shaken downwards off walls and other surfaces above the slit samplers, whereas during sweeping the organisms have to rise from the floor before they collect on the plates.

During these experiments the introduction of hypochlorite aerosol “ mists ” had very little effect on the number of dust organisms raised (fig. 1c), and the same was true of scrubbing the floor and treating it with a light petroleum “ cleaning oil ” (fig. 1d). The counts during this control period (with the exception of the haphazard sweeping day), were all of the same order, and it was convenient to take as a control figure 10

---

‡ The sampler has not yet reached its final form, and I am grateful to Dr. R. B. Bourdillon and Mr. O. M. Lidwell for allowing me to give this brief description of the earlier machines which we used for this work. Subsequent designs have shown that increased efficiency is obtained by bringing the plate closer to the slit, and experiments with these new high plate machines are in progress. The experiments described here were made with mark II machines in which the plate was at a fixed distance of 20 mm. from a thin square ground slit, as compared with the 2–4 mm. distance in the later models.

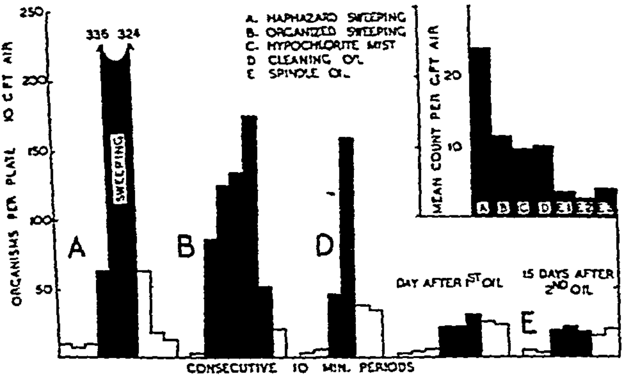

FIG 1—Air-counts during sweeping in the canteen

organisms per c ft of air growing on gentian violet blood-agar (equivalent to 170–200 organisms growing on blood-agar) The mean β-streptococcus count at this time was 0 53 per plate

Spindle-oil experiments—At the end of the control period on Dec 5, the floor was again scrubbed with hot water and soap, and a gallon of spindle oil per 1000 sq ft was then applied It was rubbed in by hand, using a well-soaked bunch of rags until the surface was not more than faintly oily to the touch, particular attention being paid to cracks between boards and in the surrounding wainscot (the same method can be applied to linoleum)

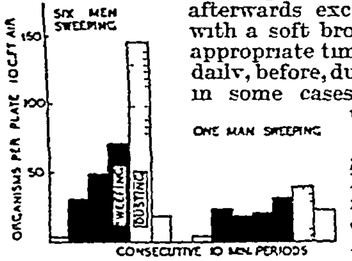

FIG 2—Effect of number of people sweeping upon dispersal of dust in the canteen

Nothing more was done to the floor afterwards except that it was swept with a soft broom and oiled afresh at appropriate times Counts were made daily, before, during and after sweeping in some cases they were prolonged throughout the day

The oil costs 2*s* 6*d* per gallon, with a reduction for large quantities A gallon is sufficient for one application to a ward measuring 20 ft by 50 ft, and is effective for periods up to two months, depending on the amount of traffic Nothing further has to be done to the floor after treatment so that the oil effects a considerable saving in labour and money

The application of spindle oil resulted in an immediate and striking fall in the sweeping peak, which remained low for sixteen days (fig 3) Immediately after the oiling the mean count was 2 4 per c ft 72 colonies only growing compared with 298 on the last control day This low level was maintained for ten days, after which there was a slow, steady rise The mean count during the sixteen-day effective period was 3 66 per c ft air, after which the count jumped suddenly to the pre-oiling level On Dec 22 the floor was oiled afresh with the same effect, the mean count during a slightly lengthened effective period of 18 days being 2 46 per c ft During this period there were two noticeable peaks (fig 3, a and b), on Dec 27, 1940, and Jan 1, 1941 On the night before each of these peaks (Boxing Day and New Year's Eve), the canteen had been used as the buffet for a dance in the adjacent hall, with the result that the tables were left littered with an abnormal amount of debris On each occasion it was necessary to clear this during the experiment and the increased counts are undoubtedly due to the dust raised from these tables over which of course the floor oil had no control When the floor was oiled for the third time, on Jan 11 a proprietary preparation was used which consists mainly of spindle oil with some apparently unnecessary additions The effective period for the third oiling was still longer—23 days with a mean count of 4 08 per c ft

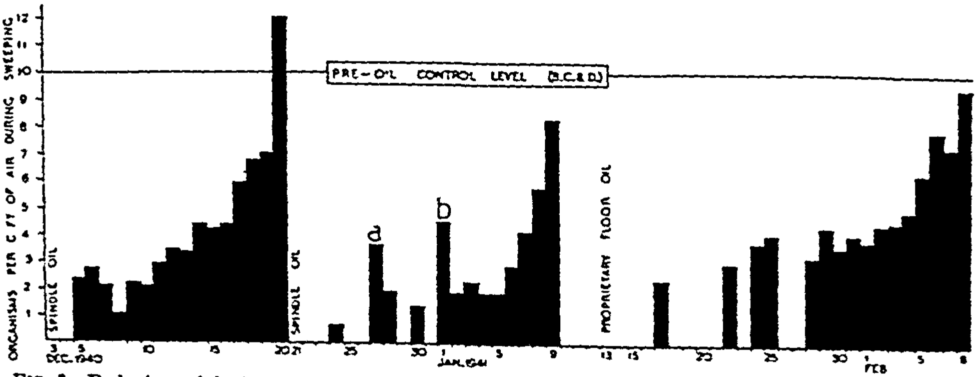

FIG. 3—Reduction of dust-organisms by the application of spindle oil to the canteen floor Mean number of organisms per c ft air each day during sweeping time

There was a significant reduction not only of total organisms but of β-streptococci during the periods when the oiling was effective, although detailed investigations of these organisms were only made during the first-oiling period Then only 49 presumptive streptococci grew on 227 plates, a mean of 0 21 per plate compared with 0 53 in the controls This represents a reduction of 2 5 1

After the oiling of the floor every part of the canteen became cleaner, since no dust was dissipated by people walking about, and any they brought in with them had only to fall to the ground to be fixed This general cleansing effect was strikingly shown by the condition of the billiard tables Immediately after the first oiling, plates exposed while the tables were being brushed gave counts considerably higher than those during sweeping itself, although the tables were 15 ft away from the machines On the third day after oiling this brushing peak was smaller and next day had disappeared nor did it subsequently return during the effective period of the oil although it had constantly been noticed during the control period (fig. 4) The oil, by retaining the dust on the floor had among other things, cleaned the billiard tables This observation may have value in relation to billiard saloons as incubating grounds for infection

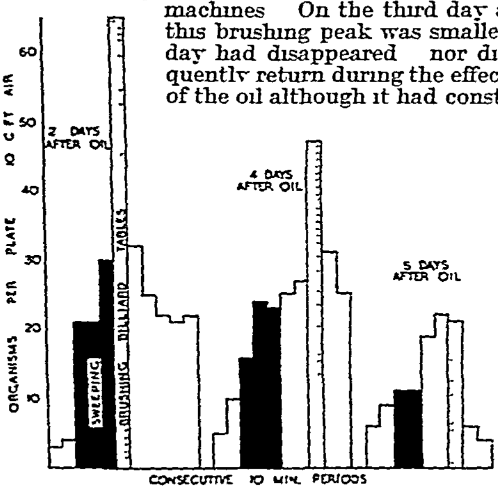

FIG 4—General cleaning effect in the canteen of spindle oil on the floor Counts before and after sweeping the floor and brushing the billiard tables

EXPERIMENTS IN WARDS

Confirmation of the effectiveness of spindle oil in laying dust organisms was obtained in a hospital ward in the course of a more extensive investigation into the problems of prevention of cross-infection A surgical ward was chosen which was divided by a glass partition and door into a 16-bed and a 10-bed section The 16-bed section was used for testing the oil and the 10-bed section as a control At the time of the experiments a mild epidemic of streptococcal tonsillitis was waning, this was mainly due to a type-6 streptococcus, but some patients had exhibited a type-3 infection All the patients at some time or another had given positive throat swabs, and the most likely source was an old chronically suppurating mastoid in one corner of the ward Counts were made simultaneously in both wards, the patients either sitting quietly or lying in bed at rest After a series of control observations the beds were straightened (not properly made but the counterpanes shaken and put straight), counts were made during and after this The wards were swept out half an hour later and the sweeping peak counted (fig 5) On every day and in each ward the same sequence of events occurred in the quiet periods the counts were low, approximately half of the total organisms being type-specific streptococci, during bedmaking a cloud of organisms was thrown into the air, the streptococcus count being more than doubled and the total organisms rising to more than 400 per plate Sweeping in the control ward caused a similar peak in the counts with a rise in the numbers of streptococci in the air In the oiled ward, however, the sweeping peak was almost non-existent Similar results were obtained in a small, single bed cubicle, in which test plates during sweeping grew only two or three streptococci compared with nearly 150 per plate before oiling

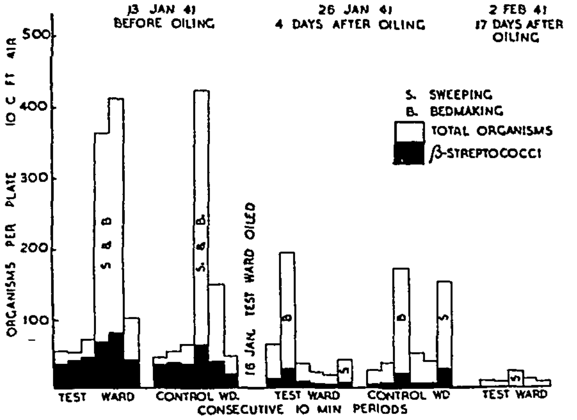

FIG 5—Air-counts in control and oiled wards, showing peaks during bedmaking, and the satisfactory effect of oiling the floor on the count during sweeping An epidemic of streptococcal tonsillitis was present during the earlier counts

DISCUSSION

Spindle oil can be applied to both wood and linoleum; if used directly on concrete it soaks in rapidly and the effect is soon lost, experiments are in hand to find an efficient proofing substance which will prevent this rapid absorption By using it on wooden and linoleum-covered floors the number of organisms projected into the air during sweeping is considerably reduced, and the reduction lasts for increasing periods with each subsequent application, up to a maximum of six to eight weeks The physical dust-laying action is more prolonged than the bacteria-laying effect shown by these experiments After a fourth oiling of the canteen floor the effective dust-laying period ran well into the seventh week, and even at this time counts showed a mean of only 6 5 organisms per c ft of air during sweeping—which was still below that obtained during the pre-oil control days During the control period the dust swept from the floor was dry and powdery, it spread widely and rapidly throughout the air and every part of the room became dusty After oiling the character of the dust was changed it was darker and matted together in large particles which did not rise at all during sweeping (fig 6) It is on this purely physical aggregation that the effectiveness of the oil depends, for the viable pathogens are firmly fixed to the dust particles and so cannot be spread into the air The floor continues to weep minute traces of oil throughout its effective period, at what seems to be a fairly constant rate Analyses of total ether-soluble or chloroform-soluble substances in oiled dust showed little difference up to 29 days in the wards, although there was approximately a 50% reduction in the well-worn parts of the canteen in a fortnight

The oil itself is not bactericidal, serving merely to retain the organisms in the dust They are still viable and may be pathogenic so that the dust must still " regarded as a potential source of infection and should disposed of suitably" (van den Ende et al 194

Spindle oil imparts a pleasant, dark, matt colour to ordinary boards, and the final surface is not slippery There may be a slight slipperiness for a few hours immediately after oiling but this rapidly disappears We have opened the canteen as soon as two hours afterwards, and neither there nor in the wards have we had a fall or accident for a period of more than four months The opinion of men on crutches or on Bohler irons is that the floor surface is much prefe able to polished ward floors Dr van den Ende kind measured the coefficient of friction between our floors an both rubber and leather soles, and compared it with un treated and polished ward floors He showed that ther was no significant difference to worn leather soles, bu that the oiled surface was slightly more slippery to rubber shoe (table III)

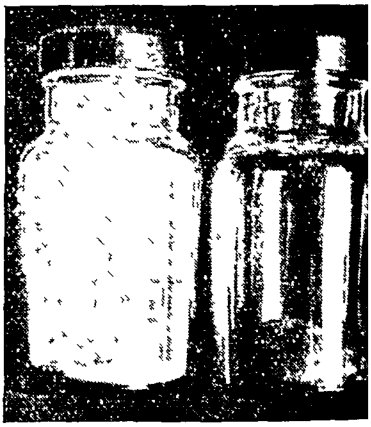

FIG 6—Dust from the canteen floor befo (left) and 29 days after (right) treatme with spindle oil Note absence of du cloud in the oiled sample Both bottl were shaken immediately before t photograph was taken

The ward experiments demonstrate two point first, that large numbers of pathogenic organisms a present in the air of such wards, and secondly, th every common event such as bedmaking or sweepi causes a further cloud of organisms to be projected in the air (cf Cruickshank 1941) At the time of t counts shown in fig 5, dust assays yielded betwe four and five million β-streptococci per gramme Su dust is, therefore, a potent reservoir of infection and mu be respected and treated as such The application spindle oil to the floor does much to minimise this danger, and should prove valuable in controlling the spread o infection not only in hospital wards, but in any place where large numbers of people are collected for any length of time

TABLE III—COEFFICIENT OF FRICTION (λ) * OF OILED AN UNOILED FLOORS (VAN DEN ENDE)

Site	λ (mean of 4 readings)	
	Worn leather/floor	Rubber/floor
Canteen		
Worn oil	0 698	0 917
Fresh oil	0 719	0 816
Ward		
Polished	0 684	1 105
Untreated	0 633	0 983
Oiled	0 652	0 861

* Ratio of force (F) required to move one surface over the other to the total force (W) pressing the two surfaces together $\lambda = F/W$ where λ = coefficient of friction

SUMMARY

The effect of spindle oil on wood floors has been tested over a period of months, both in a crowded canteen and in hospital wards In every case there has been a significant and prolonged reduction (about 80%) in the number of organisms projected into the air by sweeping This reduction applies both to the common dust saprophytes and to pathogenic streptococci

The effective period of the oil is shown to increase with each application up to a maximum of about two months, depending on the amount of traffic on the floor The cost is low and is more than offset by the saving in floor polishes

The oil can be applied to all wood floors, provided polish is removed beforehand, and to either glossy or cork-inlaid linoleum The basis for primary application is 1 gallon per 800–1000 sq ft floor space

Attention is drawn to the number of pathogens which may accumulate in ward dust, and it is suggested that the use of spindle oil on all ward floors would remove much of the danger of infection from this source Its use in any crowded place, such as air-raid shelters, factories and large stores, would have a similar effect and would result in a general cleansing of the air

The value of 1/500,000 gentian violet blood-agar as a selective medium for aerial counts is confirmed, and a brief description is given of the slit sampler, a new piece of apparatus for making these counts

I wish to thank Major General H. Marrian Perry, director of pathology, Army Medical Services, for permission to carry out this work, Colonel E B Marsh for his help, the workers at the National Institute for Medical Research, especially Dr C H Andrewes, Dr R B Bourdillon, Dr M van den Ende and Mr O M Lidwell, Ph D, for their coöperation and the loan of apparatus, and my assistants, Sgt H G Stevens and Cpl T Bury, for their help in the laboratory

PUNCH PROSTATECTOMY

W E. M WARDILL, M B Durh, F R C S
CONSULTANT IN GENITO URINARY SURGERY AT THE NEWCASTLE GENERAL HOSPITAL

THE surgical treatment of bladder-neck obstruction, whether due to adenoma, carcinoma or fibrosis, has given rise to floods of discussion and avalanches of literature The sole conclusion has been, until recently, one or other form of suprapubic or perineal removal Any intelligent man, whether lay or medical, who is approaching the prostatic age views the result of all this discussion with horror Many attempts have been made to side-track what is undoubtedly an ordeal for patient and surgeon alike In 1935 Gershom Thompson and his colleagues at the Mayo Clinic reported a series of 451 consecutive cases without a single death in which prostatic obstruction had been treated by means of the cold punch The operation is carried out endoscopically, usually without any external incision, and it allows of the patient being out of bed the day after operation The treatment can almost be described as ambulatory Confinement to hospital is a matter of days rather than months

Many of us tried to emulate the example of the Mayo Clinic, but most of us fell short It seemed then either that Gershom Thompson and his colleagues were reporting too favourably on their cases or that prostatic disease in America was different from that in this country But on visiting the Mayo Clinic with Mr T J D Lane, it became clear that the results they were attaining outstripped anything we had seen This paper is an account of an attempt to follow the example of Thompson, Emmett and their colleagues We have tried to observe fully the instruction generously given in the Mayo Clinic, and any shortcomings cannot reflect on either the operation or the teaching we received

OPERATION AND AFTERCARE

Most of our cases are admitted to hospital either with, or threatened with, acute or chronic retention of urine On admission a catheter is passed if necessary and, if there is much residual urine, is left in situ Blood-urea examination is carried out, a blood-urea of 100 mg per 100 c cm or less can be ignored so long as urinary output is satisfactory and the other aspects of the case are favourable Routine X-ray and physical examinations are made, and in the absence of contra-indications a low spinal anæsthetic is administered and the prostate and bladder are examined endoscopically Digital rectal examination is often entirely misleading and affords little indication of the degree of obstruction or the amount of prostatic tissue which must be removed to effect restoration of micturition Using endoscopy, diagnosis is made on the operating table and treatment is planned accordingly The Gershom Thompson resectoscope can be used for examination of the bladder, the prostatic urethra and in most cases the ureteric orifices

It consists of an outer sheath carrying an electric bulb and a diathermy electrode A fenestrum is cut in this sheath near its distal end and into this prostatic or other tissue can be introduced by manipulation The inner sheath is removable and ends in a razor sharp cylindrical knife for the purpose of excising such tissue as is ensnared in the fenestrum A continuous flow of water passes through the instrument so that the field is constantly clear Portions of divided prostatic tissue are washed into the bladder, and when the bladder has become distended with water the pieces are released through the instrument during the process of emptying Cutting is continued until the prostatic capsule is exposed and until there is no longer any prostatic tissue within reach. In the interest of the patient an arbitrary time limit of 45 minutes is applied

The aim of the operation is to restore function, so that as much of the enlarged prostate is removed as possible This, in many cases, must amount to about four-fifths, in some as much as 64 g has been removed at one sitting During the course of the operation the bladder becomes choked with prostatic tissue and excision must be interrupted in order to suck the pieces out by means of a large syringe As there is a constant flow of water bleeding points can be identified easily and coagulated by the diathermy electrode At the end of the operation all small vessels are carefully coagulated, the bleeding being satisfactorily controlled, the instrument is removed and a Foley catheter inserted

After-treatment is of paramount importance The bladder and the indwelling catheter must be kept free of clots by repeated irrigation In some cases this may mean washing every 10–15 minutes This is continued until the urine becomes clear and no clots are left in the bladder The nurses who carry out this procedure must be properly trained in it Asepsis is maintained by using a closed drainage system, the catheter being drained into a bottle which the patient is able to carry about with him Most patients are out of bed the day after operation and are allowed to walk about the ward or sit in comfortably heated alcoves Slight rise of temperature after operation is not uncommon but can usually be controlled with sulphonamide The catheter is removed between the second and fourth day The patient is then expected to pass water himself Usually, 6 hours after removing the catheter, he is asked to micturate and the amount of residual urine is checked If a considerable quantity remains in the bladder the catheter may either be left in for a day or two longer or catheterisation may be repeated every 6 or 12 hours until the residual urine is slight If at the end of 6 or 7 days voiding is still unsatisfactory more prostatic tissue may have to be removed, but I now rarely find this necessary Commonly, at the end of a week the patient declares himself satisfied with the ease of micturition and the force and strength of his stream, and it is not unusual for him then to be discharged from hospital. One patient was so satisfied at the end of 4 days that he refused to waste any more time in hospital

DANGERS AND DISADVANTAGES

Urethral stricture, incontinence, recurrence of prostatic obstruction and fistula into the rectum are all mentioned as complications of punch prostatectomy Urethral stricture occurs in one of two situations in the meatus or at the penoscrotal junction Meatal strictures are due to the attempts to force a large instrument through a narrow meatus, they are prevented by simple preliminary meatotomy, and their cure is equally simple Strictures at the penoscrotal junction are due to the necessary manipulation of a large instrument at a point where the urethra is normally fixed and consequently acts as a fulcrum It is usually easily dealt with by the passage of a bougie or by internal urethrotomy This complication occurred in 4 of my series of 230 cases

The danger of permanent incontinence as the result of punch prostatectomy is negligible I have twice seen examples once as the result of my own efforts in the use of a McCarthy resectoscope , and once after suprapubic prostatectomy in another clinic One case of temporary incontinence is worth mentioning

A man, aged 56, had retention unrelieved by repeated catheterisation towards the end of an attack of abortus fever His urine was foul , he had a purulent urethritis and repeated rigors I removed his prostate by the transurethral route and he left hospital on the fifth day able to empty his bladder, but for something like five months afterwards he was incontinent Examination by pin-prick showed anæsthesia around the anus, and almost certainly the incontinence was a result of the spinal anæsthetic He recovered completely

I have not been doing punch prostatectomy long enough to estimate liability to recurrence of symptoms At the Mayo Clinic recurrence is estimated at about 3% It is of little significance, because one can relieve the patient again by operation, and he is again well in a few days instead of a few months Fistula into the rectum has never occurred among my cases

FATALITY

In my 230 cases, all subjected to punch prostatectomy according to the method of Gershom Thompson, 24 died (10 4%) This statement requires amplification It has been my practice to offer punch prostatectomy to nearly every patient who presented himself with gross signs of bladder-neck obstruction It appeared to me that the risks attendant on this operation were not much, if at all, greater than those facing a patient subjected merely to suprapubic drainage without subsequent removal of the prostate Thus my series included many poor surgical risks I found, too, that increasing experience of the operative technique and organisation of the after-treatment of the patient—both of which take time to acquire and develop—brought a reduction in the fatality

Of the 24 deaths, 19 occurred in the first 130 patients , these were operated on while the clinic was accommodated in the annexe of a general surgical ward largely concerned with the surgical treatment of bronchiectasis, pulmonary tuberculosis and empyema Cross-infection of the ordinary surgical type was inevitable, and in addition 3 of my patients succumbed after operation to a *Bacillus aertrycke* infection The causes of the deaths were as follows —

Pulmonary abscess plus pyuria	1
B aertrycke infection	3
Instrumental injury	2
Cerebral thrombosis	1
Stokes Adams syndrome	1
Carcinoma of prostate (anæsthetic death)	1
Advanced renal damage	6
Gross heart failure at time of operation	3
Repeated strokes	1

The average age of all patients in this group of 130 was 68 3 years and of the fatal cases 71 4 years

In June, 1939, my clinic was moved to a separate building in which two wards and a new operating theatre had been provided solely for the treatment of these cases At the same time the organisation of the team of male nurses was completed and I was given the assistance of a surgical registrar, Mr William Cowell Among the first 100 patients admitted to the new department and subjected to prostatectomy there were 5 deaths The average age of this group was 64 9 years and of the five fatal cases 69 years I have classified these 100 patients as (*a*) those who were bad operative risks , and (*b*) those who might be reasonably expected to withstand the surgical onslaught of punch prostatectomy Criteria placing a patient in the first category were cardiovascular disease, hypertension, gross renal insufficiency, obesity and thyrotoxicosis On this basis 47 patients could be placed in the group of bad operative risks , of these 5 died (10 6%) The average age of the group was 69 4 years and of the fatal cases 69 years In the second group of 53 (average age 61 6 years) there was no mortality

I submit that punch prostatectomy abundantly justifie itself on two grounds first because where the patien is a poor operative risk, the fatality is probably lowe than for any other operative procedure which might b attempted upon him , and secondly because where th patient is in reasonable physical condition and sufferin only from bladder-neck obstruction, the operation is th safest in the whole range of prostatic surgery Th following cases illustrate the types dealt with

ILLUSTRATIVE CASES

CASE 1 —A man of 71 Every attempt at emptying hi bladder occupied 10–27 minutes He had had six previou attacks of angina pectoris , another occurred on the 10t postoperative day He left hospital on the 12th day and live in comfort till his next attack of angina carried him off 1 months later

CASE 2 —A man of 72 with pernicious anæmia Red cell 2,200,000 Blood-urea 70 mg per 100 c cm Residual urine 6 pints One month of catheter drainage while the red cel count was brought up to 4,300,000 Punch resection 24 g of prostate removed A year later he was fit, enjoying lif and carrying out his work as a farmer

CASE 3 —Aged 75, with a suprapubic tube, cardia ischæmia and bronchiectasis Prostatectomy refused o many occasions by far seeing surgeons Punch prostatectomy , recovered , now has closed bladder and is enjoying life

CASE 4 —At the age of 70 this patient had had a suprapubic cystostomy Prostatectomy refused on grounds of unfitness At 77 he underwent punch resection with excision of the suprapubic sinus , wound dry and patient emptying bladder in 7 days

CASE 5 —Toxic goitre with septic urine and stone in th bladder Punch prostatectomy and stone crushed Recovered

CASE 6 —Inoperable carcinoma of the stomach Retention of urine for 8 days Punch resection , left hospital o the 8th day

DISCUSSION

It will be clear that several of the cases quoted wer entirely unfit for any serious operation on account o senility or gross cardiovascular disease, and would neve have been fit for suprapubic enucleation Many patient in the series of 230 had foully infected urine and som had calculi which were crushed and removed at the tim of prostatectomy Another advantage of the punc operation is that patients are encouraged to get out o bed , as Mayo and Gershom Thompson[1] say, old me "are like a foundered horse , if they get down it i difficult to get them up, and their strength ebbs awa rapidly" The average postoperative stay of m patients in hospital has been just over 12 days , this figure includes long-stay patients who have been detained for social reasons

Punch resection is an operation carried out on the best surgical principles it is done under direct vision with the operative field constantly in view , incision is by means of a sharp knife and bleeding points are seen and arrested All this sounds simple, but the operative technique is difficult to acquire , in Gershom Thompson's opinion, to put a resectoscope into the hands of a man who is not prepared to study its use is like giving a submachine gun to a small boy who has been reading "Deadwood Dick" Success demands a team and a carefully trained team, and to embark on the operation without such skilled aid is to court disaster But, putting surgical considerations aside, the operation has long been demanded by the patient in America and is now rightly being demanded in this country

SUMMARY

Punch prostatectomy is the operation of choice for bladder-neck obstruction, whether due to cancer, prostatic hypertrophy or median bar It is carried out by an instrument introduced into the urethra and almost invariably without any external incision

---

[1] Mayo, C H and Thompson, A *Coll Pap Mayo Clin* 1935, 27, 351

The period of confinement to bed is 1–2 days and the verage duration of stay in hospital about 12 days

The operation can be used on patients who are bad urgical risks and is not contra-indicated by the presence f calculi or infected urine

The safety of the operation excels that of any other nethod of surgical treatment available

CALCIUM AND PHOSPHORUS STUDIES IN THYROTOXICOSIS

AND AFTER SUBTOTAL THYROIDECTOMY[*]

J DOUGLAS ROBERTSON, M D , D Sc St And , D P H.

It is now well established that in thyrotoxicosis there is a disturbance of the mineral metabolism of the body, producing an increased excretion of calcium and phosphorus The evidence for demineralisation was based on an osteoporosis of the skeleton demonstrated radiologically and at autopsy, and on calcium-balance studies where the output of calcium far exceeded the intake The literature has been reviewed by Aub and his collaborators (Aub, Bauer, Heath and Ropes 1929), and more recently by Beaumont, Dodds and Robertson (1940) Although many serum-calcium determinations have been carried out, the results produced little evidence to suggest that much decalcification was taking place There is no unanimity about the level of serum calcium in thyrotoxicosis, whether it is raised, lowered or normal Aub and others (1929), Hunter (1930) and McCullagh (1928) stated that the serum calcium was normal, Leicher (1923) and Wade (1929) found it low, the latter maintaining that the hypocalcæmia varied directly with the degree of toxicity of the case, while Montanari (1928) and Means (1937) noted an elevation Observations on the effect of subtotal thyroidectomy on the serum calcium again by no means agree, various authors finding postoperatively a rise, a fall or no change Aub and others (1929) stated that the serum inorganic phosphorus is within the accepted normal limits in thyrotoxicosis

In the present inquiry, a series of 14 cases of thyrotoxicosis were studied before iodine or other treatment ad been given and again after subtotal thyroidectomy y this means each case studied would act as its own ontrol The serum calcium and inorganic phosphorus ere estimated in each case

Results —Table I gives the findings before and after peration, with the basal metabolism and calcium excretion In table II the results are summarised and compared with those of the 60 normal controls discussed in the first paper in this series[1] It will be seen that the mean serum calcium and mean inorganic phosphorus in the untreated stage of thyrotoxicosis are lower than the normal means, and that after subtotal thyroidectomy the respective means rise and approach normal Calculated according to Fisher's P test (1938) the difference between the serum calciums before and after subtotal thyroidectomy is significant ($P < 0\ 01$) The difference before and after subtotal thyroidectomy is also significant in the case of the inorganic phosphorus ($P < 0\ 01$) If now a comparison is made between the postoperative results in the thyrotoxic patients and in the normal controls, by applying Fisher's P test it is found that there is no significant difference in the serum calciums ($P > 0\ 2$) or in the inorganic phosphorus ($P > 0\ 3$)

DISCUSSION

In studying the serum calcium and inorganic phosphorus in thyrotoxicosis and their respective variations after subtotal thyroidectomy, the relationship and control of the parathyroid glands must not be overlooked The proximity of the parathyroid glands to the thyroid renders their inadvertent removal a possibility, and it is well known that such a procedure leads to tetany and a fall *in the serum calcium* It is conceivable that milder forms of parathyroid disturbance may occur, causing a slight fall in the serum calcium but without even minor clinical *symptoms of tetany* The findings in such a case were as follows —

TABLE II—FINDINGS IN TABLE I COMPARED WITH THOSE IN 60 CONTROLS

—	No of cases	Serum calcium			Serum inorganic phosphorus		
		Mean (mg /100 c cm)	Standard deviation	Range (mg /100 c cm)	Mean (mg /100 c cm)	Standard deviation	Range (mg /100 c cm)
Untreated thyrotoxicosis	14	9 71	0 46	9 1–10 8	3 17	0 44	2–3 5
After subtotal thyroidectomy	14	10 52	0 45	9 8–11 2	3 74	0 37	3 2–4 7
Normal controls	60	10 39	0 27	9 9–11 1	3 83	0 39	3 1–4 8

	Serum calcium (mg /100 c cm)
Untreated thyrotoxicosis	9 4
1 week after subtotal thyroidectomy	8 7
3 months after operation	10 2

Likely causes of this fall in serum calcium soon after operation unaccompanied by the clinical manifestations of tetany are trauma to the parathyroid glands through manipulation during the operation , and disturbance in the blood-supply to the parathyroid glands from œdema, blood-clot, or infection In order to avoid any such immediate postoperative disturbance in the serum calcium, the cases reported in table I had their postoperative blood analyses done several months after the thyroid was removed It is possible that the conflicting results of various workers on the behaviour of the serum calcium after subtotal thyroidectomy may be explained by the phenomenon described above

A statistical analysis of the blood-serum determinations in untreated thyrotoxicosis appear to leave no doubt that the serum calcium and inorganic phosphorus are diminished and that successful subtotal thyroidectomy in the absence of any parathyroid disturbance brings these blood constituents back to within normal limits In the present series no relationship was found between the depression of the serum calcium and the severity of the thyrotoxicosis such as was reported by Wade (1929)

Competent authorities are agreed that to promote health and to allow for ideal calcium retention an average of 1 g of that mineral should be taken every day, and that this amount should be increased to 1 5–2 g in pregnancy and lactation In thyrotoxicosis there is an excretion of calcium far above normal It seems reasonable to include as part of the treatment of this disease the administration of calcium in sufficient doses to raise the intake well above the normal optimum of 1 g daily, and to exceed 2 g daily when thyrotoxic patients become pregnant

---

[*] This is the second paper in a series of four For references and methods of estimation see the first paper, Lancet, July 26 1941, p 97

[1] *Lancet* July 26, 1941, p 97

SUMMARY

There are hypocalcæmia and hypophosphatæmia in active untreated thyrotoxicosis

In the absence of any impairment of the parathyroids, successful subtotal thyroidectomy brings about a rise in the serum calcium and inorganic phosphorus to the normal level

A temporary fall in the serum calcium may take place after subtotal thyroidectomy without clinical manifestations of tetany This is probably due to trauma to the parathyroids or to a disturbance in their blood-supply from œdema, blood-clot or infection

The heavy calcium loss in thyrotoxicosis suggests that a higher intake than the normal optimum of 1 g daily should be taken in that condition

THE TREATMENT OF SUPERFICIAL GRANULATING SURFACES

ARTHUR EDMUNDS, C.B., M S Lond, F R C S
CONSULTING SURGEON TO KING'S COLLEGE HOSPITAL, SURGEON AT CUCKFIELD HOSPITAL

IN treating injuries, especially burns, one often has to deal with extensive granulating surfaces, which are as a rule infected Dressings are painful and trying to the patient, especially when they have to be changed frequently In this condition I have used this modification of the Carrel-Dakin method with success

Two thin pads of gauze (A—B) are required, about six layers thick, and some small rubber tubing (C), tied up at one end and perforated for a few inches with small holes made by a strap punch—the ordinary Carrel-Dakin tube in fact These tubes are laid on one of the gauze pads as in fig 1, so as to divide the surface of the pad into approximately equal parts Each is fastened in place by two sutures (D) The other pad is then laid over the tubes and the two pads are tacked together round the edge, allowing the tubes to project at one corner as in fig 2 The pad is then sterilised

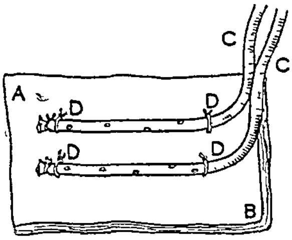

FIG 1

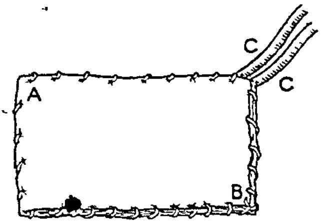

FIG 2

In applying these pads, the wound is first covered with a layer of "tulle gras" or coarse muslin, impregnated with Vaseline, using enough to prevent it from sticking to the wound surface and yet to leave the meshwork of the gauze patent The pad is then soaked in ½% chloramine, the excess fluid being lightly expressed and laid on the vaseline gauze Over this a piece of jaconet or rubber sheeting is laid The dressing is completed by a layer of wool especially arranged round the jaconet, and a bandage, through which the tubes project

The gauze is then kept moist and supplied with fresh antiseptic fluid by injecting the solution down the tubes —e g, 1 oz every six hours The quantity and the time will of course vary with the case This process entails no manipulation of the part and if the solution is warm is usually quite painless, and nothing more need be done for several days Usually the pads want changing every three days, and it is not harmful to a patient to give gas at that interval, should the dressing be painful The surgeon may elect to change the gauze pad and leave the vaseline gauze unchanged

Under this dressing the wound granulates readily, and the spread of epithelium from its edges proceeds without hindrance. Skin grafts take well under it, and it is quite feasible to leave the whole in position to allow the grafts to "take" Partial island grafts adhere q well and extend rapidly The pads can be of any or shape with any number of tubes They can be pared beforehand so that the dressing is very rapid

Reviews of Books

Bacillary and Rickettsial Infections

Acute and Chronic By WILLIAM H HOLMES, professo medicine, Northwestern University, Chicago Lond Macmillan and Co Pp 676 25*s*

AFTER twenty-seven years of teaching medici Professor Holmes felt a not unusual dissatisfaction w the conventional textbook of medicine, in which accumulated facts are set out in a stereotyped and didac manner He was convinced that the only satisfy method of teaching is to show how medicine slo evolved and thus to learn to understand the relations of medicine to the growth of civilisation It would t be seen that there are few medical "discoveries our present knowledge represents the cumulative exp ences of many generations of priests, physicians, phy cists and philosophers, and the painstaking study a observation of many centuries In pursuance of object Professor Holmes wrote not another introducti to the history of medicine but a true textbook medicine, dealing in particular with rickettsial infectio and bacterial diseases The historical method has be followed throughout—plague, tularæmia, brucella inf tions, cholera, typhoid, dysentery, diphtheria, botulis tetanus, gas gangrene, whooping-cough, hæmophil infections and mycobacterial diseases are all considere from their first recognition down to their investigatio as recently as 1938 Professor Holmes had a fascinati style and there are few so erudite that they will not lea from this remarkable book News has just reached t country of his death two months ago, if he had lived, might usefully have applied the same technique to streptococci, gonococci, and pneumococci, the spi chætes, pathogenic worms, protozoa and viruses

Early Treatment of War Wounds

By WILLIAM ANDERSON, M B Aberd, F R C S, surg and lecturer in surgery, Aberdeen Royal Infirmary, surg director, E M S Northern and North Eastern Distric London Humphrey Milford, Oxford University Pre Pp 96 5*s*

THIS little book is mainly an account of experien gained in the last war It is too short to be more tha an outline, but it contains many practical hints whic should be helpful to surgeons inexperienced in th management of wounds under war conditions Th instructions given are clear and precise without bein unduly dogmatic, and the author obviously has a balance outlook There are some trivial errors, however, and few more serious ones The two most important advanc in the treatment of wounds—the use of the sulphonamid drugs and the closed-plaster method—are only men tioned briefly The right technique must be observe *if these methods are to be used successfully and* safely and some account of it should be included in any up to date book on the treatment of wounds A third of the book is mainly concerned with military organisation and first aid, and will be chiefly interesting to those who are serving in the Army An important place rightly given to delayed primary suture, but it is odd to find Trueta's name associated with the recommenda tion for primary suture when he has written that "it only in very exceptional cases that the wound of gun-shot fracture can be sutured" ("Treatment of w wounds and fractures," p 26) The chapters on wound *of the abdomen and chest are excellent, and* in spite *of the rather scant presentation of recent advances* this should prove a useful book

LONDON SATURDAY AUGUST 2, 1941

SINGLE AVITAMINOSES FROM MULTIPLE DEFICIENCIES

WE are accustomed to look upon a deficiency disease as a single entity, produced by lack of one essential food factor The nutrition worker, studying the vitamins in the laboratory, tries by limiting his variables to avoid complicating his results, and his animals most often receive diets as complete as possible except for the one factor being investigated The clinician, too, expects to find his examples of deficiency disease clearly partitioned off as scurvy, rickets, beriberi or pellagra But human dietaries are such that if they are short of one factor they are likely to be short of many The poor person who cannot afford the protective foods, or the person who is compelled by circumstances to live on an over-simplified tinned menu, may be denying himself most of the known vitamins, let alone the unknown ones Moreover certain vitamins have a common distribution, so that a diet composed to a large extent of white bread, for example, will be lacking in most of the vitamins of the B group, and one with no fruit or vegetables will be lacking in C, H and P Thus multiple shortcomings in the diet are not uncommon and it might be expected that these cases would present the classical signs of more than one deficiency disease But in practice patients showing such mixed signs are rare

Professor DAVIDSON in this issue describes three patients in whom a diet apparently lacking in several factors led to manifest scurvy with no obvious signs of other deficiencies On the other hand, three patients whose intestinal absorption was defective developed quite different syndromes, although there was no obvious difference between their diets What determined the symptoms in each case ? There are no doubt many factors which decide what deficiency state appears first in a patient receiving a diet lacking in more than one component The most important of these are the relative degree of each deficiency, the time taken for the effects of each avitaminosis to appear, and individual variations Two diets may seem much alike in their lack of several members of the B group, yet in one a special shortage of nicotinic acid will produce pellagra, while in another the nicotinic acid will be just sufficient but the lack of vitamin B_1 will produce beriberi The time taken for the deficiency diseases to develop varies considerably This is partly explained by differences in the capacity of the body to store the vitamins, so that deficiencies of the water-soluble vitamins, which are not stored to any large extent, tend to develop more rapidly than deficiencies of the fat-soluble ones But even among the water-soluble vitamins differences exist in the rate of development of signs of deficiency Thus if rats are given a synthetic diet lacking all the vitamins they will develop polyneuritis and die The effects of vitamin-B_1 deficiency, in other words, develop so soon that the other deficiencies do not have time to become apparent We must also bear in mind that people differ widely in their food requirements Some of the variations in absorption or utilisation are easily recognised and explained For instance, the absorption of vitamin K depends on an unobstructed flow of bile, the requirement for vitamin B_1 depends on the amount of exercise taken and on the amount of carbohydrate in the diet But in addition, as Professor DAVIDSON points out, there may be individual differences in absorption, synthesis, storage or utilisation which have still to be worked out Meanwhile, consideration of the relative extent of the deficiencies, and the relative rapidity with which the signs develop will often go a long way towards simplifying a puzzling case

THEORY AND PRACTICE IN CHEST SURGERY

THE high death-rate from penetrating wounds of the chest has always weighed heavily on military surgeons In a historical survey RANSON[1] showed that during the Crimean War the fatality from this type of injury was 79% in British hospitals, in the American Civil War the rate was 63% and in the Franco-Prussian War the Germans recorded a rate of 57% During the Boer War the rate in British hospitals was only 14%, the low figure being attributed to good climatic conditions and the predominance of bullet wounds During the last war the British fatality has been given as 27 5%, and in a French unit DUVAL[2] showed that improved methods of treatment reduced the figure of 70% in 1914–15 to 25–30% towards the end of the war

The Finnish campaign gave Soviet surgeons an opportunity of collecting fresh figures At a special unit in a base hospital MATSYEV and LINBERG have recorded the results of their experiences with hæmothorax and thoracic injuries respectively MATSYEV[3] analysed 184 cases of hæmothorax and found that 96 of them were closed and 88 associated with a definite pneumothorax Dyspnœa was generally present and was attributed mainly to the pressure of the enclosed fluid and air which displaced the mediastinum in addition to causing collapse of the lung Some rise of temperature was present in nearly every case even in those with no evidence of infection, in fact, only 10% were admitted to the unit with normal temperatures Severe pain, when present, was referred to the costal margin in a fifth of the cases, and in 2 cases the pain of a gastric perforation was closely simulated On radiological examination, the heart was seen to be displaced in 43 5% of the patients and this was held to be responsible for the acute distress often noted Hæmoptysis was common (75% of cases) and subcutaneous emphysema was present in 28 5% of the total Early and repeated aspiration was adopted as the routine treatment for hæmothorax, and this, besides relieving pressure symptoms, reduced the risk of secondary infection The complication of recurring hæmorrhage as the result of early aspiration was never encountered The most satisfactory time for the aspiration was found to be from the third to the fifth day after injury and 500–1000 c cm of blood was withdrawn at a sitting In just over half the cases a single needling was held to be adequate and attention is drawn to the fact that the blood is usually easily removed, and does not clot on standing Another interesting feature, which has recently been emphasised by Sellors,[4] was that the aspirated blood had a lower red-cell count and hæmoglobin percentage than the circulating blood It is noteworthy that secondary infection only occurred in 2% of the cases of closed hæmothorax though the proportion rose to 16% when there had been an open hæmopneumothorax In any case these figures compare favourably with those of Rose Bradford and Elliott,[5] who found infection in 25% of 450 cases of hæmothoraxes treated during the last war Pneumonia occurred in 17 patients in the Russian series but there was only one lung abscess Secondary breaking down of a chest-wall wound with formation of an open pneumothorax and empyema was observed in 5 cases and is rightly regarded as a very grave complication

[3] Matsyev, I E *Surgery (U.S.S.R.)* 1940, 9 106

In another paper on the Russian experience in Finland Linberg[6] reviews 972 chest injuries, of which 83% involved the thoracic cavity Only 29 (3%) of these died, and among them were 12 men who had severe wounds elsewhere He suggests that the organisation and standardised treatment had much to do with the good figures obtained Admittedly the patients who reached the special chest unit were only the survivors from a much larger group of casualties, but the opportunity to bring some two-thirds of the patients direct from the front-line posts by aeroplane was no doubt valuable Air-transport was found to be superior to motor transport in every way when it was practicable Other factors believed to contribute to the good results were the sound general condition and physique of the soldiers and the fact that most of the injuries were caused by bullet wounds rather than by shell or bomb fragments Linberg emphasises the importance of establishing special units for the treatment of chest cases and holds that good results cannot be expected when chest casualties are distributed among the rest of the wounded He insists that conservative treatment of hæmothorax has no justification, and in this his view corresponds closely with practice in this country Blood should not be left in the pleural cavity merely because it is causing no symptoms it will ultimately produce severe respiratory disability, and aspiration should never be withheld on account of the fictitious danger of recurrent hæmorrhage Where there is a "sucking" or open wound the muscle and deep layers should be closed, though the skin wound may be left open If the skin is tightly sutured, emphysema and later infection of the chest-wall planes and pleura is a dangerous complication Experimental work on animals by Verhovitch and Ignatsovskaya[7] showed that the most satisfactory way of treating an open chest wound was to repair the deeper layers of the chest wall and drain the pleural cavity by a valvular rubber tube In some cases, as a life-saving measure, they advocate early pneumopexy to minimise the harmful effects of a free and open pleural cavity Their experiments were used as the basis of treatment in Linberg's unit, with good results Foreign bodies lodged in the chest should be removed as soon as possible and at the same operation wounds in the lung or adjacent viscera can also be dealt with

These Russian papers illustrate the pitch efficiency which can be attained in a base hospit unit specialising in the treatment of chest injurie so long as the first-aid and preliminary treatment ar adequate and the patients are transported from th front line with the least possible delay

DIAGNOSIS OF CRETINISM

There is a tendency these days to give thyroi extract hopefully to almost every retarded chil when the backwardness is physical, mental or both What Wilkins and Fleischmann[1] of Baltimore ca "lack of critical analysis and an excess of enthusiasm applied to cases of dwarfism is doubly unfortunat because it obstructs advances in treatment and may raise false hopes in the parents of a mentally defectiv child The list of modern methods for the diagnosi of hypothyroidism as set out by Wilkins and Fleischmann appears formidable, but the "classical" cretin is usually easily recognised at a glance after a little experience The clinical features of hypothyroidism arising during the period of growth fall into two groups. alterations in bodily structure and alterations in functional activity The stunting in growth is well known and hypothyroidism accounted for about 25% of dwarfs in the Baltimore series after diseases of bone and cardiac, renal, intestinal, hepatic and metabolic disorders had been excluded Not only is growth delayed, but the child remains relatively top-heavy, retaining the infant's characteristic disproportionate length from symphysis pubis upwards The naso-orbital configuration also tends to remain infantile, playing an important part in determining the facies of the cretin Retardation of osseous development is an important factor in the anatomical abnormalities of the hypothyroid child, but such osseous changes are unfortunately not confined to dwarfs of thyroid origin, although treatment with thyroid will only produce a prompt effect in them Dental development is similarly affected, but according to Wilkins and Fleischmann a form of epiphyseal dysgenesis is probably the most specific of all the anatomical changes due to hypothyroidism, calcification in the epiphyseal cartilage appears in multiple small irregular foci, eventually coalescing into a single irregular centre They conclude that whereas structural changes are of great diagnostic value in most cases there is a theoretical possibility that a mild degree of thyroid deficiency may exist throughout childhood without producing any characteristic ones, so that functional activities must be studied as well

Mental sluggishness and physical inactivity are present in all cases in some degree and some improvement follows thyroid medication Cardiac output and circulatory rate are constantly diminished, but are difficult to measure The most valuable laboratory tests seem to be those concerned with basal metabolic rate, serum-cholesterol and urinary excretion of creatine Lately Tobias and Stockford[2] of Los Angeles have been seeking for the best measure of what they term the "metabolic speed" of children and have carried out a survey of carpal development, basal metabolic rate and serum-cholesterol in 216 children selected at random From a statistical analysis they find that the level of serum-cholesterol is the simplest and most satisfactory measurement of metabolic activity This is essentially confirmed in relation to the diagnosis of hypothyroidism by WILKINS and FLEISCHMANN. Not only is the estimation of the basal metabolic rate difficult in the young child of subnormal mentality but there are certain fallacies in the test when applied, for example, to obese children whose body-surface area upsets the normal standards The serum-cholesterol level offers a surer guide, for in most children with hypothyroidism it lies between 250 and 600 mg per 100 c cm compared with a range of 100–300 mg in normal children If other causes of hypercholesterolæmia, such as diabetes nephrosis or hepatic disease, can be excluded, then a serum-cholesterol level of over 300–325 mg per 100 c cm is very suggestive of hypothyroidism

[2] Tobias W and Stockford, L *Amer. J Dis Child* April, 1941, p 675

The urinary excretion of creatine is low in the hypothyroid child but there are great differences in the excretion of this substance in normal children so that as a biochemical observation in the untreated cretin it has little value A valuable extension, however, of both the serum-cholesterol test and the urinary creatine estimation is found in the results of giving a single intramuscular dose of thyroxine (2–5 mg) In the hypothyroid child a noticeable decrease in the serum-cholesterol is produced lasting about 40 days, whereas in the normal there is only a slight and transient fall Urinary creatine rises after thyroxine in the cretin but here again the normal standards are variable A still further extension can be made by the use of the thyrotropic hormone of the pituitary. Here the average daily output of creatine in the urine is studied for a control period of 1–2 weeks Thyrotropic hormone in doses of 5–10 units per kg of body-weight is then injected daily for about 10 days, and the daily excretion of creatine measured The hormone is then omitted until the excretion of creatine returns to the base level and finally the effect of thyroid or thyroxin on this level is measured In a child with hypothyroidism, thyrotropic hormone produces no change in creatine excretion or cholesterol level, presumably because the child has no thyroid tissue capable of stimulation, whereas thyroid raises urinary creatine and lowers serum-cholesterol In one type of control in the Baltimore series both thyrotropic hormone and desiccated thyroid produced changes in creatine and cholesterol levels ("positive"), in another neither had any effect ("false negative") A false negative response was found in certain normal children and dwarfs with normal thyroid function, though most of the latter gave a positive response It is clear that biochemistry offers valuable aid in the diagnosis of the cretin and should be more widely used to prevent mistakes There is one other line of inquiry which WILKINS and FLEISCHMANN do not mention—study of the anæmia of hypothyroidism and the possibility of a positive reticulocyte response when thyroid is administered to the cretin but not to other anæmic, retarded children This might prove simpler than the thyrotropic-hormone-creatine method although not as simple as study of the cholesterol level, itself in many cases quite sufficient to confirm the clinical evidence

SANDFLY FEVER

THOSE who fought in the Middle East in the last war will not need to be reminded of the military importance of that comparatively trivial disease phlebotomus or sandfly fever This acute infection, due to a filtrable virus, is conveyed from man to man by the *Phlebotomus papatasii* and possibly other species of a genus which has a bad record for transmitting disease kala-azar in India, oroya fever in Peru Sandfly fever may occur wherever the vectors exist, and in the present field of military operations is common on the Mediterranean littoral, in Syria, Palestine, Trans-Jordania, Egypt, Iraq and India Outbreaks seem to appear in two annual waves, in the late spring and the autumn Over 70% of non-immune people—and this includes most Europeans—get the disease on their first exposure to infection, about 15% of these have a second attack, and some have a third or fourth The severity of the attacks steadily diminishes after the first, and the later ones may not be diagnosable clinically By early and repeated exposures to the disease the indigenous population acquires a substantial immunity to it, and children suffer less from an attack than adults

Among non-immune Australian troops, concentrated in Southern Palestine during 1940, WALKER and DODS[1] saw many cases, in addition to those reporting sick and entering hospital there were many who were not prevented from carrying on their work In the First Australian General Hospital some 1500 cases were seen between May and November, 1940, most of these coming in July, August and September Two types of cases were noted those in which the onset was sudden without obvious prodromata, and those with prodromal symptoms lasting 24–48 hours In both types the onset was associated with mild shivering, but rigors were unusual The temperature rose abruptly to about 102·5° F. in the average case and remained up for more than three days In some cases after several days without fever there was a secondary rise of temperature with a recrudescence of symptoms lasting a day or two The physical signs include a pathognomonic facies The face is puffy and swollen and the complexion red and suffused. Conjunctival congestion is common and hence the popular names "pink-eye" or "dog disease" (*Hundfieber*) The eyeballs are tender to pressure and on movement, and are therefore kept still Frontal headache and pain in the eyes and leg muscles are so severe that sleep is impossible The tongue is furred, and in the cases reported by WALKER and DODS a striking and constant feature was the early appearance of a crop of vesicles on the soft palate, extending to the faucial pillars on each side. These vesicles are devoid of any surrounding mucosal inflammatory reaction, and cannot be regarded as peculiar to sandfly fever, for they may be seen in other virus diseases and were noted in cases of infective hepatitis in Palestine In contradistinction to dengue, where an eruption comes out during the usual secondary rise of temperature, no true morbilliform rashes were seen among the Palestine cases of phlebotomus fever A relative bradycardia was almost invariable after the first day, and an absolute bradycardia was often a striking feature towards the end of the fever, when the pulse-rate fell to 60 a minute or less **Walker** and **Dods** were unable to study the blood-picture adequately, but leucopenia affecting the granular leucocytes only is a typical finding for the first four or five days, and this is followed, it is said, by a leucocytosis up to 15,000 or 20,000 per c mm about the tenth day of the disease Treatment is purely palliative, but sedatives relieve the symptoms to some extent The mortality is negligible

---

[1] Walker, A. S and Dods L. *Med. J Aust* 1941 1, 345

The importance of this malady (apart from its unpleasantness to the sufferer) lies in its tendency to arise epidemically, for outbreaks may make it difficult to keep a non-immune force active in the field during the epidemic season Prophylaxis is difficult on account of the very small size, the breeding habits and the voracity of the sandfly vector The breeding grounds of the insects are rubble, dug-outs, cracks in walls and embankments, and sun cracks in the ground The larvæ penetrate to a depth of a foot or more in loose, slightly moist soil, and the insect hibernates in the larval stage, emerging in the spring The female alone bites, usually after dark, and its powers of flight are limited The erection of parapets, the excavation of tent and hutment floors, and similar earthworks necessary in the field of military activity may facilitate the breeding of the flies Where cracks can be levelled or filled in, especially with tar, the insects can be discouraged from breeding Blackout conditions increase the liability to be bitten, because men prefer to sit outside, on or near the ground, where the flies await them, rather than in dark tents or huts The ordinary mesh mosquito net is useless against these tiny aerial invaders and suitable nets of muslin, or of particularly fine mesh, although efficient in excluding them from a sleeper, feel close and stuffy in a hot climate Their use should, however, be insisted on whenever practicable The use of a pyrethrum insecticidal spray inside huts and tents daily, before sweeping the floors, will reduce the sandflies, mosquitoes and house flies in such places, and an electric fan where available will provide currents of air sufficient to carry the sandflies away If huts and similar dwellings can be built on piles well off the ground they will be comparatively immune from invasion by sandflies No drug, serum or vaccine therapy is available for immunisation against the disease, and the best precautionary measure against undue morbidity in endemic areas is to employ on active operations troops "salted" by previous infection

THE CAPITATION FEE

When introducing on July 15 the second reading of the bill with a long name the Secretary of State for Scotland said that the question of the doctor's capitation fee was still under consideration Actually, as Dr Anderson told the Insurance Acts Committee on July 10, the Minister of Health had already agreed to increase the capitation fee from 9*s* to 9*s* 9*d* and there is to be no further advance on this offer At the beginning of 1942 provision will be made for finding 20*s* a year as a fixed charge for each insured person 14*s* 6*d* of this will be paid into the medical pool, out of which it is estimated administration will draw 10*d*, drugs 3*s* 7*d*, mileage 4¼*d*, the remainder with luck being very nearly if not quite 9*s* 9*d* Of the additional 9*d* the larger part (5½*d*) is intended to cover the increased expenses of practice The 3½*d* is added, apparently, to compensate the doctor for the transfer of the new higher-income group (£250–£420) from his private to his insured practice Dr Anderson calculated that an extra 3½*d* all round will bring in something like 11*s* 6*d* per head of these new entrants The doctor can thus pretend that he is getting a guinea for each of them, and if he lives in a Utopia where there are 40 previously insured persons to each new entrant he may even be right Admittedly the 9*d* increment to the capitation fee has been arrived at without reference to enhanced cost of living and the Minister has given an undertaking that the basic fee will be reassessed immediately after the war

INTRAVENOUS OXYGEN

A correspondent asks why more use is *not* made of intravenous oxygen in the treatment of shock, and points out that the method has been proved practicable During the last war Tunnicliffe and Stebbing[1] worked out such a method with a view to applying it to the treatment of acute cyanosis caused by mustard gas and other respiratory irritants Using simple apparatus they experienced no difficulty in introducing oxygen into a vein at the rate of 600–1200 c cm an hour, and in cases of chronic cyanosis arising from malignant disease of the mediastinum, pernicious anæmia and so on they found that this improved the patient's colour and relieved his dyspnœa In only one case—their first—was any complication encountered, here an old man became temporarily unconscious during the administration, with extensor plantar reflexes, but he soon recovered and was none the worse The only disadvantage appeared to be that the method required the whole time attention of the administrator, and as it is now generally agreed that oxygen should be given continuously this is a serious drawback The method has since been little used, though it was revived a year ago by Singh and Shah,[2] who found that amounts up to 10 c cm a minute could be safely injected from a cylinder, or double this amount if chemically pure oxygen was used, representing some 10% of the patient's requirement They gave up to 350 c cm to six patients with pneumonia and satisfied themselves that there was clinical improvement They mention that oxygen embolism, unless carried to extremes, is not dangerous There is, then, no doubt that intravenous oxygen is practicable and reasonably safe On the other hand, its use in peace time would be confined to the patient whose functional lung is much reduced by extensive pneumonia, and such cases are rare In the treatment of shock without cyanosis it is doubtful whether the method would have any place Here the blood is fully oxygenated in the lungs, and the tissues are only short of oxygen because their blood-supply is deficient The inhalation of pure oxygen relieves this shortage slightly by forcing an extra 2–3 c cm of oxygen into solution in every 100 c cm of plasma To do this by the intravenous route would mean giving the exact amount necessary to oxygenate the hæmoglobin plus a very little more to saturate the plasma In other words, the patient would have to be given a little more oxygen than he was consuming, a procedure which would certainly produce embolism Giving a little less would be safer, but this would only relieve the lungs of their task of oxygenating the hæmoglobin, which they had previously been doing efficiently and without difficulty When the patient is cyanosed the position is different, for unsaturated hæmoglobin is avid of oxygen, and there seems a possible use for the method in cyanosed patients with severe injuries of the lungs or chest wall It is in he gassed case that it might prove most useful, and hile there is a chance that the enemy may still resort o gas warfare it would be well to have the technique orked out more fully and its possibilities explored

LIBRARIES NOW AND AFTER

AMONG the less spectacular ways in which our Ameri- an friends are helping us is in solving our library problems Many American libraries have offered individual help to their opposite numbers over here and the Rocke- eller Foundation has been outstandingly generous on a comprehensive scale Dr Arundell Esdaile, president of the Library Association, in a letter to the *Times*, has told how the foundation is financing a scheme promoted by the Library of Congress to make microfilm copies of all important manuscripts in this country, beginning with the British Museum and Public Records Office collections A project of more appeal to our profession is the survey, also financed by the Rockefeller Foundation, which the Association of Special Libraries has undertaken of technical periodicals now reaching this country from abroad, with a view to making those that are received available where they are most needed Medical libraries have been particularly starved of continental literature Our largest professional library reports that its intake of world periodicals has been reduced by half Since the fall of France no medical periodicals have come in from occupied countries and very few from Germany, so that we have had to depend on the few neutral countries to tell us about medical activity and research on the continent during the past year Letters in the American press show that American libraries are beginning to feel the pinch too European periodicals are either not being sent to them, except from Britain, or if sent are often lost in passage And this is no temporary loss, for after the war it will prove impossible to fill these gaps in the libraries Publishers of scientific journals are printing only for their regular subscribers and there will not be enough copies to go round when the gaps come to be filled The cheapening of photographic processes at last brings within the range of even a shallow library purse the possibility of filling their gaps with microfilm reproductions Under the pressure of war, commercial firms have taken up this technique for copying their records on a great scale, and libraries will benefit by the resulting drop in price Hitherto the lack of a cheap reading machine, which is now being produced, has made the microfilm an almost useless plaything except for record purposes Now it may rapidly become the vehicle for a revolution in our library services, making all books available to readers at a distance, as it is already doing through the Surgeon General's Library in Washington

London is particularly rich in medical libraries A correspondence in these columns just before war broke out showed something of the chaotic conditions out of which these libraries were only then feeling their way towards coördination At the moment they are scattered in varying degrees of inaccessibility The Rockefeller Foundation again has made possible their dispersal from the danger zone of bombed London The Royal Society of Medicine has evacuated about a third of its great collections within accessible distance of London, thus ensuring a minimum of dislocation but not a maximum of protection The Royal College of Surgeons, whose buildings have since suffered much damage, took the precaution of sending its library farther afield, where though still in being it is of little use to readers The Royal College of Physicians has had to store its library beyond access The London School of Hygiene library, the latest to join the ranks of the evacuees, aims we understand at a middle course of probable safety and limited accessibility When—in a not too distant future, we hope—these libraries return intact to London the readjustments which will be necessary will offer a unique opportunity to provide some coordinating mechanism for our wealth of medical literature Before the war it was scattered in half a dozen libraries, each of which, being a department of a semi-private institution, was necessarily restricted in its scope and in its use by the profession as a whole Just as the National Central Library acts as a clearing house for the public and academic libraries throughout the country, so the medical profession needs a centre to coordinate its libraries and make them of the fullest use to all medical men The occasion will be there immediately after the war, and in microfilm we have a new technique to exploit which should simplify the difficulties We should welcome the coming opportunity and begin to prepare the plans now for a central cooperative service worthy of our great libraries

PULMONARY LESIONS IN EXTRATHORACIC TUBERCULOSIS

IN an attempt to discover the frequency with which a pulmonary lesion, mild or latent, is associated with extrathoracic tuberculosis, Vaccarezza and Gómez[1] have studied 420 cases of hæmatogenous tuberculous disease, including tuberculosis of the bones and joints, glands, meninges, genito-urinary organs, eyes, peritoneum and skin In 90% they were able to demonstrate, clinically or radiologically, the presence of pulmonary tuberculosis In a large proportion of the cases the pulmonary lesions were active, 36% of the patients presented clinical signs of progressive disease of the lungs The findings certainly accentuate the importance of complete examination in patients with extrathoracic tuberculosis These Buenos Aires workers advocate clinical and radiological examination of the chest and examination of the sputum and gastric contents for tubercle bacilli in every case, and they urge that all patients with tuberculous disease of any part of the body should be segregated in special wards in hospitals While such precautions may be desirable for patients with active disease, it seems unnecessary to adopt them for patients who merely present (as do many healthy people) clinical or radiological signs of old tuberculous lesions of the lung, such as calcified glands at the hilum

ISINGLASS AS A BLOOD SUBSTITUTE

WHOLE blood is the only fluid that will adequately replace blood lost through hæmorrhage, but it possesses practical disadvantages in that it cannot be stored indefinitely and the danger of incompatibility can only be removed by routine blood grouping, for which there is often too little time in an emergency Dried human serum to a great extent meets the requirements of an ideal transfusion fluid, but it is not produced on a sufficiently large scale for universal use and its great value in burns and shock tends to limit its use to these conditions The ideal would be to store red cells and plasma separately, so that cells only could be used for anæmia, plasma for shock and the mixture for acute hæmorrhage Various substitutes have been tried Gelatin solution, which is a colloid, does not easily leave the circulation and has a reasonable viscosity, but it carries the danger of tetanus or anthrax infection, though one would think that this could easily be overcome by using pure bacteriological gelatin However, gum acacia was substituted, and in spite of good results during the last war it is now out of fashion because it is said to cause liver damage Crystalloid solutions do not remain for a sufficiently long time in the circulation Now we have a new blood substitute in isinglass, which is prepared from the swim bladders of fish Taylor and Waters[2] of Toronto say that it can be made sterile, is non-toxic and is practically non-antigenic In a 7%

CLOSE-UP OF SPERMATOZOA

THE electron microscope, which gives effective magnifications of 50 000 or more diameters, and has already told us much about bacterial appearances under electron bombardment, has lately been turned on the spermatozoon in the hope of resolving some of the outstanding doubts about its structure. In this apparatus magnetic-field ‘ lenses ’ replace the glass ones of compound microscopes and differentiation depends on differences in density within the specimen rather than on variation in refractive indices or colour. The conditions for examining specimens by electron microscopy are important because the vacuum, the drying of the specimen or even the electron bombardment itself may cause artefacts which can masquerade as normal structure. It seems, however, that Seymour and Benmosche[1] have seen more clearly than hitherto a normal human spermatozoon and their pictures—three are needed to include a single sperm—have, at 13,500 and 27,000 diameters, clear-cut definition. At these magnifications the pear-shaped head of the human sperm has a crater-like notch on the vertex and within it a structure less opaque than the rest of the head. The body of the spermatozoon, which when seen by refractive microscope was called the neck, is segmented, having 9–12 segments in the specimens examined. Throughout the length of the body runs a core, uniform in diameter and denser than the surrounding segments, and it is this core which becomes the tail. The tail does not end abruptly but breaks up into a blurred smudge and it is much longer than has previously been described. The belief that the body of the sperm contains a skein formation was not confirmed but the segmentation probably explains the extraordinary motility of the head as it is propelled forwards. With motion pictures Seymour and Benmosche watched the head of a spermatozoon penetrating the ovum in the first stage of fertilisation and they speculate on the possibility of the notch on the vertex containing some sort of suction apparatus which helps penetration.

EXTRA MILK

THE medical certificate required under the Sale of Milk (Restriction) Order, 1941, has come in for some criticism, and the Ministry of Food is discussing possible alternatives with the B.M.A. Extra milk, up to a limit of 2 pints a day, may only be recommended if the patient is suffering from (*a*) active tuberculosis, (*b*) silicosis; (*c*) conditions in which the patient is unable to swallow solids by reason of an affection of the mouth, throat or gullet; (*d*) gastric, duodenal or anastomotic ulcer, (*e*) illnesses characterised by high and prolonged fever; or (*f*) the results of a major operation. This list was drawn up by the special diets committee of the M.R.C. and must cover the majority of indications. It is questionable, however, whether the doctor should not have been left free to consider each case on its merits. On the other hand, it is an unenviable task to refuse milk to any patient, and the doctor may sometimes be glad of such definite grounds for refusal. The certificate when completed is handed by the householder direct to the milkman. This is intended to simplify and hasten procedure, but many patients will object to their disabilities being thus revealed to tradespeople. It would surely be sufficient if the doctor stated that the patient was suffering from one of the conditions on the prescribed list without specifying which. Members of the national milk scheme, children receiving milk in schools, and patients in hospitals and nursing-homes are excluded from the restrictions and other people who are accustomed to drink a lot of milk will automatically have a large ration, since this is calculated as six-sevenths of the previous consumption. The number of cases which cannot be met by a little readjustment within the household is therefore likely to be small.

Colonel (temporary Brigadier) ALEXANDER HOOD succeeds Lieut.-General Sir William MacArthur as director-general of the Army Medical Services on Aug. 1. Brigadier Hood graduated from the University of Edinburgh in 1910 and received a commission in the R.A.M.C. two years later.

SYSTOLIC MURMURS

IN his Honyman-Gillespie lecture in Edinburgh last week Prof. D. M. Lyon said that up to the end of last century any cardiac murmur was usually taken to indicate heart disease. Then began a swing in the opposite direction and the study and significance of murmurs became derided. He believed that a balance was necessary. Murmurs were produced when turbulence was introduced into the blood-flow. This could be caused by changes in the speed of flow, or the viscosity of the fluid, and by constriction of the channel. Mere roughening of the surface of the channel did not produce eddying. *Mitral systolic organic murmurs* varied from soft gentle blowing sounds to loud rasping sounds according to the state of activity of the heart muscle. The murmur of dilatation was softer and not so well propagated. *Tricuspid systolic organic murmurs* were relatively rare; they were of higher pitch than mitral murmurs and poorly propagated. In view of the reputation of the tricuspid valve as an escape valve it was surprising that tricuspid murmurs were heard so seldom. *At the aortic valve* organic narrowing was relatively rare and most systolic murmurs were due to dilatation of the aorta along with thickening of the valve, especially the slight projection of a fibrous or calcified cusp. Pulmonary systolic murmurs were still rarer and most were congenital. *Functional murmurs* were always systolic except for the murmur of pulmonary incompetence sometimes found in conditions of raised pulmonary blood-pressure. They were mostly feeble and poorly conducted. They were probably found in 3% of all recruits and in 80% of athletes after severe exercise. In children various reports put the incidence at between 10 and 60%. The *cardio-respiratory murmur* was heard along the left border of the heart and beyond; less frequently over the right side. It often occurred in healthy persons. In quality it resembled interrupted breath sounds of which it was really an accentuation. An interrupted puffing or whiffing sound was present during the whole of inspiration and might extend into expiration. It was usually heard best with the subject in the upright position and stopped if he held his breath. Exercise increased its intensity which, however, was very variable at different examinations. *Hæmic murmurs* were caused by turbulence due to decreased viscosity of the blood; they were heard at both base and apex but the mechanism must be different—turbulence of the flow at the aortic and pulmonary valves and dilatation of the mitral valve. Hæmic murmurs should not be diagnosed in the absence of severe anæmia. When the heart was over-active or too rapid functional murmurs might be heard at the apex. These were common during excitement and in “ soldier’s heart.” A thrill might be palpable and the first sound appear rough. These features disappeared when the heart-rate fell and must not be taken as indicating mitral stenosis. The murmurs of hyperthyroidism and fever were of the same nature. Pulmonary functional systolic murmurs were mostly faint and poorly conducted and were largely due to slight variations in shape or deformity of the pulmonary vessels, that was apart from cardio-respiratory and hæmic murmurs. They were found largely in children and young people with plastic chest walls and might be produced by pressure of the stethoscope. It was important to remember the subclavian murmur heard beneath the clavicle when the arm was raised.

[1] Seymour, F. I., and Benmosche, M. *J. Amer. med. Ass.* 1941, 116, 2489.

solution it has a higher osmotic pressure than plasma and its viscosity though less than that of whole blood is greater than that of plasma, enabling a higher blood-pressure to be attained Taylor and Waters have recorded favourable results when using isinglass to replace lost blood in dogs and maintain that in many cases the dogs' lives were saved by it Their solution contains 7% of isinglass, 0 25% of sodium bicarbonate and 0 75% of sodium chloride in distilled water This is said to be isotonic and has a pH of about 7 2 They are careful to point out that the fate of isinglass in the body is not known though they believe that it may be used by the tissues If this is the case a valuable substitute for blood will have been discovered It seems, however, *that rather than new substitutes* what is required is an efficient manufacturing, distributing and clinical organisation, so that those materials which are already available may be used to better advantage

PRESENT POSITION OF VENEREAL DISEASE

THE possibility of an increase of venereal disease in war-time is an inevitable source of anxiety to all who *remember the black record of previous wars No doubt* this was in the mind of those who organised the meeting of the Medical Society for the Study of Venereal Diseases on July 26 when Colonel L W Harrison utilised his presidential address to consider the present trend of incidence of venereal diseases in England and Wales No-one is better fitted to review the situation than Colonel Harrison by reason of his length of experience and his breadth of outlook He struck a reassuring note at the outset by pointing out that since the outbreak of war venereal diseases have not increased to anything like the extent which we feared As regards syphilis, before the war we had good reason for believing that the great *majority of early infections* in civilians coming under medical care in this country were being dealt with in the treatment centres A suspicion that undetected syphilis might be rife in country districts far from treatment facilities had been disproved by the fact that although they had since the war been infiltrated with service personnel, munition workers and evacuees they had not been found hot-beds of venereal disease

In a comprehensive review Colonel Harrison showed that in 1939 the number of cases of early syphilis dealt with for the first time at the civilian centres in England and Wales was 4986, a decrease of some 45% since 1931 and less than a third of the number in 1920 Collateral evidence of this decline was found in the diminishing rôle of syphilis in killing infants, their death-rate from this cause had fallen from 2 03 per 1000 in 1917 to 0 2 in 1939 As regards service infections, the admission-rate for syphilis in the Navy stationed at home fell from 8 1 per 1000 per *annum in 1921 to 1 96 in 1936, the latest year* for which published figures are available In the Army at home the syphilis rate fell from 9 8 per 1000 per annum in 1921 to 0 9 in 1937 In the Air Force during the same period the rate for primary and secondary syphilis fell from 4 1 to 0 5 There are other causes at work in diminishing venereal infection among recruits, but the higher rates in stations abroad suggest that the decline is some index of the improvement in the position at home Returns from civilian clinics indicated, said Colonel Harrison, that from the outbreak of war up to the end of March, 1940, the fall in the syphilis rate slowed down, during the last twelvemonth there has been a definite increase among both males and females As a result of all his calculations Colonel Harrison came to the conclusion that male syphilitic infections had increased in England and Wales in 1940 by about 27% and that the total increase in both sexes was about 23%

Civilian cases of gonorrhœa were fewer but when service cases were added the total males showed an increase of 9–10% It was, he thought, disturbing to find that the centres had dealt with fewer females in
1940 in spite of the clear evidence of increased in
in the males On the other hand, as Colonel H
and subsequent speakers recognised, the moder
treatment of gonorrhœa has made recourse to
practitioners so much more common that clinic st
for this disease are now a very imperfect indica
incidence and comparisons with previous yea
fallacious Where, he asked, was this incre
venereal disease occurring and is the existing sys
treatment centres *sufficient ? The best infor*
available comes from the lists of places where
men stated they contracted the disease The
whelming majority of places where more than 1(
tions had occurred were already provided with trea
centres *Nevertheless the details* showed *that*
deal of sporadic infection was occurring in places
range of the clinics And yet in some places
relatively heavy infections of service men had

danger of injustice to individuals If improved me
of diagnosis and administration can enable local autho
ties to eliminate the hard core of recalcitrant offender
without injury to the public a great advance will hav

performance of his duties Such is the wording of rule 9 of the " Rules applicable to Schedule E ' which lie hidden away in a corner of the act The judge would not allow the expenditure upon subscriptions to these bodies to be put so high The point arose again in July when a London County Council divisional engineer sought to deduct the amount of his subscription to the Institution of Civil Engineers He could fairly maintain that he could not have obtained his appointment unless he had been a member of the institution or had held other approved qualifications that his duties involved his maintaining a recognised professional status and that it would be unprecedented and inconvenient for a man who held the post of divisional engineer to relinquish his membership of the institution while so engaged The court, however accepted the Crown's contention that it was not enough to show that the office-holder must necessarily incur the expense of membership of the institution in order to obtain or keep his post or to win promotion It seems a pity that the L C C did not deduct the amount of the subscription before paying him his salary , his tax assessment could then have been reduced *pro tanto* Hitherto it has been supposed that the tax-payer can deduct his subscription to a professional body if the terms of his appointment require him to be a member of the body The law is careful not to allow him to deduct expenditure (for example on books) which he incurs merely for the purpose of fitting himself to take up the appointment

For the medical man who is in private practice and is not an official the case is different Rule 9 of the Rules applicable to Schedule E is no longer the relevant standard It has been usual to allow him to deduct subscriptions to professional journals to the British Medical Association or to a medical defence society Outside these established concessions, the revenue authorities allow the deduction of a subscription to a professional body when satisfied that the body spends the money on objects which would have justified deduction if the tax-payer himself had spent his money on them As usual there is a working arrangement by which particular bodies are accepted as being within this category Much indeed of our income-tax law consists of working arrangements recognised in departmental practice That is why the Income Tax Act with its long tail of amendments by subsequent Finance Acts is no very helpful guide to the tax-payer even if he could comprehend its complicated clauses That is why too, the chartered accountants who specialise in income-tax matters thrive upon the complication of the law They know the kind of deduction which the Inland Revenue officials habitually allow Thus not only must the tax-payer pay tax, but he must also pay experts a fee for helping him to do so

SCOTLAND

ADVICE TO EDINBURGH GRADUATES

Prof D K Henderson gave three golden rules to the new graduates at Edinburgh on July 16 He said do not arrogate to yourselves a knowledge which you do not possess , *do not be afraid to say you do not know* , do not hesitate to ask for a little time to think things over Every scientist and research worker would subscribe to these precepts In issues involving life and death they could not afford to be casual or thoughtless though an emergency might sometimes compel them to act promptly For the young doctor sense—implying exactness and soundness, power and promptitude of mind—must be the master faculty But he must have genius too a real turn for his profession, and presence of mind How man lived, moved and had his being was still an unsolved mystery, but they could be certain that he should not be thought of as a stomach heart lungs or bowels, but as a whole personality His likes and dislikes, his loves and hates his fears and hopes his aspirations and disappointments might supply the key to his more mundane complaints Man himself how he was constituted, how he reacted and responded biologically to the stress and strain of life whether physical or psychological, must be studied as well as the symptoms associated with individual organs Medical work was far from being a rule-of-thumb affair For success it required elasticity of mind and a many-sided approach It had been said that every doctor should be a good sociologist He should also be something of an educationist and if he was he would steer clear of over-specialisation and recognise the social as well as the scientific side of medicine

DIPHTHERIA IMMUNISATION

A new effort is being made to stimulate interest among parents of children who have not yet been immunised against diphtheria and to have the children immunised before the winter. Out of a total child population of 1,124 500 in Scotland 529 679 or about 47% have been immunised The percentages in individual districts vary and in some places the goal of 80% has been reached and exceeded On the whole the proportion of school-children immunised is higher than of pre-school children and the proportion in rural districts is much higher than in the towns Dr Andrew Davidson chief medical officer to the Department of Health for Scotland recently announced a new and much appreciated service In Coatbridge and in Perth medical officers with the aid of mobile vans carrying the necessary equipment had immunised the children in their homes The new publicity campaign is to be carried out by the Department of Health with the coöperation of the Ministry of Information They will use a film called ' Defeat Diphtheria " which shows the complications which may arise from neglect to obtain medical advice

Parliament

Last Touches to the Pharmacy Bill

When Mr Ernest Brown on July 22 brought forward a new clause to the Pharmacy and Medicines Bill that the professional side of the bill should be enforced through the Pharmaceutical Society he was doing so at the request of the House and the clause was quickly approved Clause 2 of the bill gives power to the statutory committee of the society to consider cases of misconduct or of conviction for a criminal offence where the pharmacist concerned was temporarily unregistered by reason of the non-payment of fees Captain G S Elliston moved a new clause extending this principle to corporate bodies carrying on a chemist's business and a second clause requiring the chairman as well as the majority of the committee to be satisfied before a company is penalised Both clauses were quickly accepted Mr Brown then moved important amendments designed to enlarge the scope of the definition of disclosure by including quantities and laying down that so far as possible the constituents should be expressed in everyday language But Mr Brown was sure the House would not wish him to lose accuracy for popularity and he had therefore fallen back on disclosure in terms which would be readily understood by a doctor, chemist, or any other expert Disclosure was required in one of the following ways

(1) Where a medicine or a constituent was a poison in the Poisons List the name to be used was then required in connexion with the labelling of the poison ,

(2) Where it was not a poison, but was described in the British Pharmacopœia or the British Pharmaceutical Codex, the description at the head of the relevant monographs must be used

(3) Where it was neither a poison nor described in the British Pharmaceutical Codex, then the accepted scientific name, or other name descriptive of its true nature, must be used

The second part of the amendments required the quantities of the named constituents to be disclosed either by giving the percentages of the medicine or by stating the actual amounts When a medicine was supplied in the form of pills or tablets the percentage of the constituent in the medicine the quantity in each pill or tablet , or the quantity of the constituent in the whole article must be disclosed

Sir Francis Fremantle in thanking the Minister for the amendments said that we must rely on the press to continue its useful function of interpreting technical phrases to the general public It was to the credit of the proprietary trade that they had accepted the principle of quantitative disclosure The amendment

Special Articles

PUBLIC-HEALTH PROTECTION IN THE U S S R[1]

EVERY citizen in the Soviet Union has the right to free skilled medical care, from outpatient hospital service to special treatment in clinic or sanatorium The state pays the salaries of all medical workers and maintains all the hospitals, polyclinics, dispensaries, institutes and health resorts as well as providing funds for research A single authority thus controls all medical services in town and country, as well as measures for controlling infectious disease, sanitary inspection, housing, industrial medicine, communal feeding centres, maternity and child welfare, health resorts, research and medical education Prophylaxis forms the basis for all the public-health measures, and the attack on first causes—poor working and living conditions and so on—has succeeded in eliminating much of the disease of former times An eight-hour working day has been introduced, and all workpeople get an annual holiday of two or four weeks on full pay Employment of children is prohibited, and that of adolescents is restricted Pregnant women and young people are not employed in dangerous occupations or on night-work Social insurance is widely developed, offering financial security in illness invalidity, pregnancy and old-age Supplementary state grants have been introduced for nursing mothers

First-aid or health-protection centres have been established in all factories, mines and the like, and the doctors and nurses attached to them control the sanitation of workshops, and public dormitories and dining-rooms, keeping a watchful eye on working conditions and safety measures, as well as studying the causes of industrial accidents and occupational diseases, devising means for their prevention, examining all new workers on their arrival and at regular intervals afterwards if they are adolescents or engaged on harmful occupations They also teach the principles of hygiene to the workpeople, arrange for special jobs for those in poor health, and are at hand to give first-aid in cases of accident or sudden illness

Workpeople who require special treatment are sent from the centre to the polyclinic or hospital, or to the night or day sanatoriums where they can spend the rest of the day after working hours in receiving medical attention The centre can also arrange for a workman to get his food in one of the dietetic dining-rooms, the cost of the special diet being partly or fully defrayed by the state

The district or factory polyclinics provide outpatient medical services for all citizens in their area If the patient is not fit to attend he can telephone to the polyclinic for a doctor who will attend him at home A single type of outpatient record-card is used throughout the hospitals of the Union It has space for a complete history and diagnosis, and for the doctor s prescriptions and recommendations, so that when a patient is admitted to hospital his record-card comes with him from the outpatient clinic, and when he is discharged the full details of any inpatient treatment he has received are set down for the information of the doctor outside

CONTROL

Public-health protection is under the control of the People's Commissariat for Public Health of the Union, but this body exercises direct jurisdiction over only certain particularly important (from the state point of view) medical and sanitary institutions, educational and research institutes and health resorts and over the manufacture of surgical instruments, and equipment and drugs Other medical institutions are controlled jointly by the Union commissariat, the local soviets and the commissariats of the autonomous republics concerned The scheme thus includes the all-Union commissariat, the individual commissariats of each republic, the territorial, regional or city departments of public health, hospitals, polyclinics, factory health-protection cer rural medical centres and the visiting doctors A head is the people's commissar for public health, wh member of the government He is also chairman o collegium which meets once a week to implement gov ment decisions and draft the instructions to be sent to the other public-health bodies On technical tions the commissar is advised by a scientific me council, and he has the power to enforce what meas he thinks fit to improve the medical services and en that all hospitals and clinics are using the most effe methods of diagnosis, treatment and prevention commissariat has also set up various boards and dep ments to deal with special problems, such as skin venereal diseases, as well as with the administratio the urban and rural hospitals, &c A special depart controls all the special hospitals and other institut for the treatment of tuberculosis

The entire network of anti-epidemic institutio anti-plague hospitals, centres, trains and laborato anti-brucellosis stations, anti-malaria, anti-insect anti-rat measures, and bacteriological laboratories-under the direct supervision of a special board at commissariat, and this body also supervises the pro tion of vaccines and sera Another department of commissariat undertakes the sanitary inspection of factories, shops, public dining-rooms and so on, and its representatives—qualified doctors—in all the la industrial concerns Its inspectors have power to put immediate stop to any infringement of the regulati they meet with

Much attention is given to the welfare of mother a child, and every district and every large works has nurseries and kindergartens The best sanatoriu throughout the Union have been set aside for childr A good deal of research is being carried out into mot and child protection, particular attention being gi just now to painless childbirth There is a vast netw of maternity homes and special maternity wards hospitals, antenatal and postnatal consultation cen special hospitals and health resorts for children, infa homes, nurseries, kindergartens and milk-kitchens obstetrical departments are responsible for supervi the working of the law prohibiting abortion sanatoria and spas are owned by the state and su vised by a single department, which is also in charg the balneological research institutes at Sochi Pyatigorsk

The whole drug-manufacturing industry is mana by the Commissariat for Public Health, and all phar cies belong to the state No patent medicine can offered for sale until it has been passed by a med body, and new drugs of all kinds must be checked in state institutes and clinics before they are offered to public

The economic and social life of the country is regula by the third five-year plan, which lays down what su are to be spent on training doctors and nurses, on erection of new medical institutions and the like the basis of the general plan the Commissariat for Pu Health works out a plan for each republic, this in t allocates funds to the constituent regions, and so down to towns and districts and to the individ hospitals and clinics

MEDICINE AND THE LAW

Income Tax and Subscriptions

IN Simpson *v* Tate it was decided many years that a medical officer of health could not deduct from income-tax assessment (Schedule E) the money he sp in subscriptions to the Royal Society of Medicine, Society of Medical Officers of Health, the Royal Instit of Public Health and the Association of County Medi Officers of Health In vain he protested that he co not keep himself up to date in sanitary science and pu health unless he enjoyed the facilities given by th bodies in the form of printed journals and periodi discussions The Income Tax Act will allow deduction only of sums which the tax-payer is oblig to expend "wholly exclusively and necessarily in t

In England Now

unning Commentary by Peripatetic Correspondents

ORE the outbreak of war the duties of a group were to arrange for the staffing of all hospitals in rea, to decide the functions of each hospital and to plans for the evacuation of hospitals and their ble equipment After the outbreak of war he ed movements of patients between the hospitals in roup, and since the scheme embraced municipal tals, he worked in close cooperation with his cal officer of health This city possesses two itals, each having roughly 500 beds I well remem- the hospital officer telling me on my appointment evacuation would be easy instead of 1000 beds I uld have 2000 beds in the reception area This ed optimistic About 1300 beds are the maximum he immediate reception area, and most of them are ipied by civilian sick When severe air-raids have urred, we have had to transfer cases to the outer ption area under direction from the regional hospital er They go in converted-bus ambulance and motor oulance convoys In the autumn of 1940 a " com- nications " exercise was carried out in central control anks to our vigorous imaginations the numbers of posed casualties far exceeded any that have occurred actual raids Not only were motor ambulance con- ys summoned, but an ambulance train was brought to take slightly wounded cases to the farthest towns the region Nothing like this large scale transfer has r been necessary in practice, but we enjoyed it at the e The first twelve months of the war passed without at are officially called " incidents," and it was not til September and October, 1940, that there were raids e more memorable of these occurred on four successive hts The municipal hospital, which is unfortunately ced in a very vulnerable spot, had several bombs pped in the grounds which shook it up considerably. ter this we decided that top floors must not be used for tients, and it was reduced to the rank of a casualty aring station with only 100 beds

The first noteworthy raid occurred in November On ching central control I learned that one of the hospi- s had been hit, so I walked over to find out what had ppened I was met by the R S O who asked reason- y enough if he could possibly go on operating in the ualty theatre The windows were blown in, a bomb the boiler house had put an end to central heating and water mains had been severed Seeing there was no it, no water and no heat, but more than enough sty night air, it was fairly easy to decide that further rating in this theatre was out of the question In the other theatres *operating* continued for a short time ger, but the snowfall of plaster flakes from the ceiling n stopped that The only thing left to do was to ange for the evacuation of everyone in the morning tients and nurses were evacuated during the day, and dusk the last patient—a German navigator—had been t off to a military hospital " If only I could tell m how good you all are," he said to the nurses during raid, " they would'nt drop bombs on the hospitals "

Ve learned some useful lessons from that raid ght we, for example, to send street casualties from the phery into the two main hospitals ? There were ng arguments against it the hospitals lay in the tre of the city and it was a case of moving the injured of the frying pan into the fire , street obstructions m craters, with consequent diversions of traffic, npered the movements of ambulances It is difficult realise how isolated one is and how hard it is to anise Although we thought everything had been vided for, the scale of destruction proved we were ng The outside ambulances duly arrived at the boundary, but they were held up there until guides ld be found to lead them through a Hampton Court ze of strange streets

or future occasions we arranged a rendezvous for bulance convoys, enrolled guides and despatch carriers go on foot or bicycles The medical officer of health I drew up two schemes for evacuation depending on severity of the raid In small raids, we decided, es should be taken as before to the nearest city pital In larger raids all cases except those in the immediate vicinity of the larger hospitals should be taken out to the nearest aid post, and from there transferred to a reception hospital The aid posts, chosen by the medical officer of health, formed an almost complete chain round the circumference If communication with central control should break down, the second plan was to come into force automatically

This reshuffling of Government posts annoys me Our minds naturally picture the politicians we read about daily as Gilbert and Sullivan figures—we know well enough what a First Lord looks like, or a Lord Chancellor —then suddenly we have to think of them changing their dresses and their characters Take Mr R A Butler's appointment to the Ministry of Education. For years he has been the perfect popper-up with the obvious answer, " The sub-subcommittee of the chairman's subcommittee of the Non-Intervention Committee . ," he was particularly good at that sort of thing Suddenly we have to picture him as a sort of super-schoolmaster Has he had anything to do with education ? My dear fellow, what has that got to do with it ? These politicians have such colossal minds, such terrific experience, that aided by their experts—why, technical knowledge can be an absolute handicap , he'll read up education in a couple of nights One's exasperated mind falls back on fantasy The Lord Privy Seal is in a four-post bed, looking anxious " You've got pimple-itis " I say sternly, laying down my stethoscope, " *and must be operated on at once* I'll 'phone Lord Nibs " " But-but I thought he was a physician," says a wan voice from the bed " Yes, yes, he is, but in a crisis like this we must get the best brains He reads a lot, you know Broad view, and so on, and his wife's a charming woman "

* * *

Cerebral arteriosclerosis, not uncommon among centenarians, appears to be singularly lacking in Mr Punch He has his moods, of course, and his off-weeks, but those who say that he is not what he was are, in fact, condemning themselves Of his infancy and adolescence much has been written , as a child he was often befittingly ingenuous and in the insolence of young manhood he was something of a snob, but he got over it In his maturer years he introduced us to the early Milne which set a new standard in humorous journalism Some of it was thin stuff, but the Rabbits it may be remembered lowered an egg-proof curtain during their amateur theatricals , nice humour that, judged by whatsoever standard you please There are still plenty of us who gratefully recall our weekly doses of R C Lehmann and E V Lucas , and the apparently inexhaustible flow of " Evoe " who coined that immortal description of athletes as " nothing more nor less than martyrs to exercise " There was also a young A P H , more naïve and less propagandist in those days, who assured us that the grasshopper *couldn't* make its peculiar noise by rubbing its knees together since he himself had tried it in the bath and it didn't work In the stern days of O S the *occasional* contributor had to be accurate and not facetious There were more misses than hits, of course, but an MS returned with " suggestions " pencilled in the margin could be regarded as a near-miss, whereas an acceptance was never couched in more positive terms than " I *think* I can use " There was once a young man who devised, collected and hopefully dispatched some 50 paragraphs of would-be charivaria " One retained for possible use " was O S 's devastating reply

* * *

This sex business is getting beyond a joke My elderly Dandie bitch, who ought to know better, has suddenly and without warning become as irresistible as Cleopatra and Helen of Troy combined, with the result that the garden and—if you don't watch out—the house itself are infested with an assortment of ardent curs of every shape and size Among the most neurotic and least successful of her suitors is a small nondescript terrier who, owing to the proximity of bigger and stronger competitors, sees fit to woo from a distance This he does by giving vent to a series of indignant yaps which unless steps are taken continue for days and nights on end until he finally becomes so hoarse that he can't speak at all Air-gun slugs shrewdly aimed at his posterior produce only temporary relief and I am had the unique advantage of satisfying everybody, including Sir Francis

Sir THOMAS MOORE made another effort on behalf of the herbalists After an assurance from Miss F HORSBRUGH that there was nothing in the bill to prevent herbalists from treating people and selling medicines if they disclosed their contents he withdrew his amendments, though hinting that his protégés might make themselves heard in "another place"

Sir FRANCIS FREMANTLE in expressing satisfaction at the passing of the measure paid a tribute to the work of Captain Elliston He pointed out that it was not true that the medical profession had a monopoly of treatment Everyone could get treated, or maltreated, as much as he liked The Medical Acts had been passed, not to give privileges to the medical profession, but to give protection and guidance to the public Mr GRIFFITHS once more pointed out that the best protection was a positive medical service, making all that science knows available to all on equal terms

The bill was given a third reading unanimously and has since been read a second time in the House of Lords without change

QUESTION TIME

Teaching of Mothercraft

Sir FRANCIS FREMANTLE asked the Minister of Health if he had considered the report from the National Association of Maternity and Child Welfare Centres urging the immediate need of the teaching of mothercraft to schoolgirls, and if he would consult with the President of the Board of Education with a view to putting this recommendation into operation —Mr E BROWN replied I have noted the report with much interest Its recommendations fall mainly within the province of the Board of Education, but I shall be glad to consult with the president on the steps that it may be possible to take towards carrying them out

Sir FRANCIS FREMANTLE then asked the President of the Board of Education if he was aware that teachers, probation officers, doctors and social workers were generally anxious for the teaching of mothercraft to be given to schoolgirls as the best means of attacking juvenile delinquency, and whether he would arrange for such teaching to be given throughout the country —Mr R A BUTLER replied A chapter of the Board's handbook of suggestions for teachers on health education is devoted to mothercraft and I shall continue to foster such instruction as is practicable for schoolchildren

Women Medical Officers in the Forces

Sir FRANCIS FREMANTLE asked the First Lord of the Admiralty why women medical officers recruited to the Navy were not given the rank, status and title accorded to male medical officers in the service —Sir VICTOR WARRENDER, deputy secretary to the Admiralty, replied Only one woman medical officer is employed and she holds the relative rank of surgeon lieutenant, R N V R, and receives the pay of an officer of that rank She wears the distinguishing stripes of a surgeon lieutenant on her sleeve

Sir F FREMANTLE Do you not recognise that the distinction is insufficient for the duties of the officers and that the Admiralty are behind-hand in not having women medical officers ?—Sir V WARRENDER If we were to supply women doctors to look after the W R N S personnel it would mean duplicating the medical staff, and that would lead to inefficiency The W R.N S were canvassed on their wishes in the matter and only 2½% expressed a wish to have women doctors —Dr EDITH SUMMERSKILL That shows how reactionary the Navy is

In answer to a similar question, the Secretary of State for Air said that women medical officers commissioned for service with the medical branch of the R.A F have the status of officers, and the relative ranks pertaining to their duties, and they are addressed as medical officers Sir F FREMANTLE I should like to know why the title is not given as for male medical officers, and whether it is decent and congruous that a woman medical officer should have to be addressed as Miss Smith, medical officer, with the relative rank, squadron-leader or whatever it may be ? Sir A SINCLAIR In the women's services, such as the Women's Auxiliary Air Force and the nursing services, special designations apply to the members Sir F FREMANTLE asked if he did not recognise that women medical officers are in a quite different position from other women officers

Radiological Examination of Recruits

Mr GRAHAM WHITE asked the Minister of Labour i were facilities for the radiological examination of for His Majesty's forces, and if he would consider such examinations general —Mr ERNEST BEVIN re Where they consider it desirable the medical boards examine recruits for His Majesty's Forces may radiological examination before determining the grading A suggestion that all recruits should have a logical examination was considered last year by the advisory committee under the chairmanship of Lord and the committee decided that its adoption was impracti —Mr GRAHAM WHITE But not undesirable ? Mr B No, it is a question of equipment and staff

National Loaf in the Army

Sir STANLEY REED asked the Secretary of State for W he would give the extent to which the national loaf national flour were used in the feeding of the Arm Captain H D R MARGESSON replied Arrangements being made for at least a quarter of the bread supplied to Army to be made from the new national flour, and this be gradually increased as stocks of white flour are used

Analgesia in Childbirth

According to the returns made up to Dec 31, 1940, 49 of 188 local authorities had made arrangements approved the Central Midwives Board for instructing midwives in administration of analgesics Apparatus for administer analgesics was supplied by 33 authorities during 1940 compared with 21 during 1939 Under special arrangeme made by the Ministry of Health with the National Birthd Trust, 43 machines have been supplied to emergency mate nity homes in which the staffs are adequately trained in t administration of gas and oxygen

(Mr BROWN replying to Dr SUMMERSKILL)

General Medical Council Appeals

Mr T E GROVES asked the Lord President of the Cou whether, having regard to the right of dentists, pharmac and certain other professional persons, to appeal to courts against disciplinary decisions, appropriate steps wo be taken to amend the law and give doctors a similar right Sir JOHN ANDERSON replied I am not satisfied that th is any general desire in the medical profession for s legislation at the present time

Silicosis Research

Mr JAMES GRIFFITHS asked the Minister what progr had been made by the Medical Research Council in th investigation into the problem of silicosis among coalminers Sir J ANDERSON replied The medical part of the investig tion was completed some time ago and the draft report h now been revised for publication at an early date Th environmental studies have also been completed except f the examination of a small part of the material collecte and these form the subject of a second report which is bei prepared It would be impracticable to summarise the resul of a complicated and highly technical investigation.

Milk for School-children

Mr H BROOKE asked the Parliamentary Secretary to th Ministry of Food whether any arrangements existed for makin sure of an adequate weekly milk supply for children over fiv not attending a school where the state aided school milk scheme was in operation —Major G LLOYD GEORGE replied This is one of the matters which is being considered in the review of milk distribution arrangements which the Minister is now *making*

SYMPOSIUM AT MARX HOUSE —On Aug 16 and 17 the science faculty of Marx House will hold a discussion on Frederick Engels's works, "Dialectics of Nature" and "Origin of the Family, Private Property and the State" On Aug 16 at 3 P M Prof H Levy, D Sc, will open a discussion on philosophical methods and the sciences, and at 7 P.M Prof J B S Haldane, F R S, will speak on modern scientific achievements and their bearing on dialectical materiali On Aug 17 at 10 A M Prof George Thomson will open a discussion on historical materialism applied to primitive communal society and in the afternoon Prof J D Bernal, F R S, will summarise the results of the discussions which take place at Marx House, 37A, Clerkenwell Green, London, E C 1

RADIODERMATITIS

SIR,—There is good reason to believe that the risk involved in setting fractures or removing opaque foreign bodies under the fluorescent screen is not generally appreciated, and as the practice appears to be on the increase the council of the Faculty of Radiologists desire to draw attention to this risk.

That the risk is a real one is shown by reports of cases of X-ray dermatitis of the hands and faces of surgeons in the E.M.S. in this country. There is also a report from Leddy and Rigos (*Amer. J. Roentgenol.* May, 1941, p. 696) of the Mayo Clinic who record 55 cases of X-ray and radium dermatitis in doctors in the period 1919–34 and 80 from 1934–39. Of the latter group only 5 were radiologists, the remainder physicians and surgeons. Of these 80 cases 15 were the result of X-ray therapy, the balance being occupational—i.e., resulting from diagnostic procedures or handling radium; 46 cases (only 3 being radiologists) were directly due to manipulations under the screen, either setting of fractures or removal of foreign bodies; in 30 cases the injuries to the hands had gone the length of ulceration, 21 of the ulcers being malignant.

As no screen apparatus in use at present, not even the recent model using indirect vision, can protect the hands against the rays if the fractured limb is being manipulated or the foreign body being removed while the current is on, these two procedures should be actively discouraged. In both, the operator's hands are inevitably exposed to the direct beam of the rays. The council of the faculty are of opinion that these methods should be used only in exceptionally difficult cases, and that when used the manipulation and viewing with the current on should alternate so that the hands are never in the direct beam. The council also recommend that a radiologist well versed in the factors involved should be in attendance when these methods are used. Further safeguards are the use of an adequate filter, small milliamperage, and low kilovoltage—e.g., 2 mA at 55 kV peak. Experiments show that the output is very greatly reduced if these factors are adopted.

M. H. JUPE,
Hon. Secretary Faculty of Radiologists.
32, Welbeck Street, W.1.

ALOPECIA IN FRIGHTENED CHILDREN

SIR,—In your columns recently much has appeared about war neurosis, with evidence for and against such a disease entity. Two unusual cases of alopecia areata in children under 7 sent by Dr. Twiston Davies, dermatologist to the Children's Hospital, Brighton, have recently been examined by me at the child guidance clinic of the Lady Chichester Hospital. In each case the loss of hair followed bombing or machine-gunning incidents. In two such young children an anxiety syndrome caused by war conditions is of importance, and I do not know of any similar record in recent medical literature.

Girl, 2½.—Elder of two sisters, no known family history of instability. Previous history: Normal development, healthy but always a bad sleeper, dominated by mother. Sept. 1940: Father in the Army; mother during a bad raid on Camberwell sheltered in the cellar, when the house was shaken by a near hit she wakened the child by shouting in her panic. Three days later the child's hair was observed to be falling out and she talked incessantly of bombs, shelters and so forth. The child rapidly lost all her hair; the mother was advised to evacuate to the country, when there the child's hair grew well under *safe conditions*. Jan. 1941: The patient and her mother came to Hove, the child not anxious and hair grown over the whole scalp. April, 1941: Ten days after a raid all previous nervous symptoms returned and the patient again began to lose her hair. While being examined at the clinic the wind rattled the window and the child asked anxiously if it was due to bombs and should not everyone take shelter.

Girl, 6½.—Youngest of five (three dead). Both parents over anxious, worrying temperaments. The father has been unemployed frequently during the last ten years. *No other* family history of instability. Previous history: Normal development; otitis media when teething at 12 months; chickenpox, measles and whooping cough before school age. School report, very good but over anxious. Patient dependent on and dominated by her mother. During the autumn of 1940 the patient had screamed frequently in her sleep when the sirens sounded at night. The parents often rushed the child and her brother downstairs or under beds for safety when bombs dropped near by. *On another occasion at school* she was snatched up hurriedly by a teacher and rushed to a shelter. March, 1941: Alopecia areata noticed about 2 weeks after the road was machine-gunned by an enemy raider when the child was returning home from school. The patient was very frightened and inarticulate on arrival home.

It would be interesting to hear if other cases of alopecia areata had been found when examining children from badly blitzed areas.

Hove, Sussex. C. LAMORNA HINGSTON.

SUCCESS IN SKIN GRAFTING

SIR,—An annotation in your issue of Nov. 9, 1940, in which the method of skin grafting adopted by Szutu and Chen was taken as a text, implied that pressure is an essential factor in secondary skin grafting and that the area treated must be completely covered by a single graft. I challenged the accuracy of these contentions but you rightly refused to publish a bald denial. I now enclose a reprint of an article which I submitted for publication in August, 1940 (*Brit. J. Surg.* 1941, 25, 585) wherein both these questions are discussed.

Unless dead tissue can be removed by some other process than separation brought about by tissue reaction the elimination of sepsis may not be possible or advisable. Rapid control of sepsis, however, in a denuded area will permit the equally rapid application of successful skin grafts with directly proportional effect on contraction and deformity, to say nothing of the time saving with attendant effect on wastage and expense. The use of a single graft will be impossible in large areas. In some sites adherence to this whole-piece policy may be actually detrimental. Taken in conjunction with the ability to dispense with pressure in secondary skin grafting the fractional method of application will permit such a sectional mechanism as for instance the fingers to be dealt with in a sectional manner. No concession can be made to sectional structure if it is considered essential for success in skin grafting (secondary) to deal with the fingers as units, a system which leads to harmful immobilisation.

To my mind, the solution of the problem of secondary skin grafting is the elimination or the rapid control of sepsis, and it is to this end that all available effort should be directed.

London, W.1. PERCIVAL P. COLE.

"SCIATICA"

SIR,—I fully agree with Mr. Kellgren that sciatica is a clinical syndrome which in the majority of cases is caused by a pathological condition localised not in the sciatic nerve proper. In my opinion we have to distinguish between a true sciatica of nervous origin and a pseudo-sciatica or muscular sciatica of muscular origin. I described such cases of muscular sciatica in the *Lancet* (1940, 2, 326) and the *Practitioner* (1941, 146, 167). I differ from Mr. Kellgren in several important points. In my experience patients do not complain of deep pain, but mostly of superficial pain. From my experience as a patient I can say that deep pain, although felt, cannot be localised at all. The superficial pain can be localised approximately only and rarely corresponds to a real dermatome or dermatomes. It is, too, noteworthy that most patients asked to map out the painful areas hesitate for a short time, and only slowly and grudgingly point to the painful skin areas. According to O. Foerster (*Brain*, 1923, 56, 1) the dermatomes overlap to such an extent that section of a single root in man is not followed by loss of sensibility at all, because the corresponding skin area (dermatome) is also supplied with fibres from the neighbouring roots. Numbness, pins-and-needles and so on are not necessarily of nervous origin. These symptoms can be and often are of purely muscular origin. According to C. M. Bazett and B. McGlone (*Brain*, 1928, 51, 18) puncture of fascial planes causes sensations resembling those of some forms of neuralgia. They experimented on themselves without a local anæsthetic, thus differing from Kellgren's technique. I have shown clinically (*loc. cit.* and *Brit. J.*

seriously contemplating the use of shot-gun cartridges loaded with dried peas The soldiers billeted on us lovingly finger their rifles but there are limits Another of her suitors is an undersized and not very successful near-spaniel, but for some reason or other the lady will have none of him Two sheepdogs, built on collie lines, she finds equally attractive, but mutual jealousy permits neither to steal a march on the other It is remarkable how they sneak into the house, and for the matter of that out of it, without sustaining any mortal injury from well-aimed kicks or heavy missiles thrown at them While these two are glowering at each other a small Scottie contrives to make a good deal of hay, and on present form he seems most likely to be the father of the next unwanted litter Of course, it is all very educative, for the children The other day my small daughter ran into the house wringing her hands and crying "Daddy, Daddy, come at once Jenny has been married five times!"

* * *

Our hospital was very heavily bombed three months ago My laboratories got a direct hit and are levelled to the ground with the work of 30 years—records, materials, apparatus and specimens—lying somewhere under the debris The hospital is determined to carry on and repairs are being effected as quickly as possible Meanwhile the various departments, including the path lab, are functioning in a block of empty flats nearby There is in the grounds an old disused patient's shelter left derelict from the early days of open-air treatment It has a good tiled roof and a steel framework, but no walls or (in fact) anything else We have started to put walls round it and turn it into a temporary pathological department, and I think it will not be a bad one, though it will cover only about a third to a quarter of the area of the original It has been passed by the necessary authorities for the duration of the war, and will constitute our second temporary home

* * *

"From ghoulies and ghosties and long-leggity beasties and things that go bump in the night good Lord deliver us"—so runs the old Cornish prayer written at a time when cockchafers were the only things of importance which might go bump in the night Sleeping out in a tent is, in my view, always a hazardous and uncomfortable proceeding but my wife says it is good for us, so of course we sleep out in fine weather The other night I was just getting off to sleep, after destroying a couple of hundred culices in the air or on the ground and reinflating the pneumatic mattress which had died on me, when I heard the stealthy tread of a wild beast which crept up and began to gnaw one of the guy-ropes Seizing a slipper I sprang up prepared to sell my life dearly He was easily picked out in the moonlight crouched ready to spring and lashing his tail, but seeing that I meant business he thought better of it and slunk away among the gooseberry bushes He was a field-mouse, as a matter of fact, but as I explained to my wife it would have made no difference to me had he been a tiger or a parachutist She smiled proudly—or perhaps cynically, I cannot be positive which Enigmatically would be a better word

* * *

The school M O was examining evacuees As two boys were shown into the room he took one glance at them and then his face lit up as he exclaimed "Aha, twins!" One of the boys disdained any reply, merely sniffing and wiping his nose on the back of his hand The other, with a look of contempt for this prattling doctor, said flatly "No, we're *not* twins" The S M O, palpably deflated, motioned to the boys to be seated while he took their names and addresses Having finished this, he stood up with a look of triumph on his face "I told you so!" he exclaimed, "You're as like as two peas, you have the same birthday, and you have the same father and mother You're twins" "No, we're *not* twins," said the more talkative one emphatically "Well, what are you?" demanded the medical officer irritably "We're all that's left of triplets"

CIVIL DEFENCE AWARDS—For brave conduct in civil defence the M B E has been awarded to Dr Isobel MacAlister of Wallasey, and the George medal to Dr Percy Horsburgh of Nuneaton

Letters to the Editor

PENSIONS APPEAL TRIBUNALS

SIR,—In the House of Commons on July 16 Fraser again besought the Minister of Pensions to independent appeal tribunals to deal with claims f pensions The Minister admitted the need fo tribunals and said he would establish them t if he could, the lack of medical men with su experience was his main difficulty He estimate to set up two tribunals in each region he would n doctors and a further 25 to prepare precis of th for the appellants In addition to the doctors risters and a lay staff of some 400 would also be As far as the doctors go I am confident that the could find the men Retired practitioners, whe tacts with clinical work are not so remote as to them useless, are aching for a chance of doing som Even men of seventy or over are not necessarily and work such as this needs, above all, experience judgment Reference to the national register (w seems to be curiously overlooked) would verify th existence and availability The 25 precis writers wo surely be easy to find, it does not require much phy energy to sit in an office and deal with familiar Experto crede I should volunteer at once if I got chance, and my name has been on the register

Henley on Thames — ALFRED COX

MEDICAL SERVICE IN NEW ZEALAND

SIR,—From time to time paragraphs appear in THE LANCET reporting, with greater or less bias, or at least with the colour of strong personal opinion, the alleged course of events in the medical world of New Zealand Most of these reports bear on their face their ow partisan character, and it is needless, therefore, to urg careful readers to treat them with due circumspection It is, for instance, misleading to picture the government' comprehensive Social Security Scheme as being frustrated by the antagonism and criticism of the medical profession The main part of that scheme is working smoothly and to the general satisfaction It has gone far toward giving the people of New Zealand, in a unique degree proper safeguards against such hazards of life as sickne unemployment and poverty through loss of the brea winner or old age

Even in the sphere of medical benefits, while admittedly there are inadequacies, it is well to rememb the very substantial steps forward already taken W now have a free maternity service for all mother Public hospitals provide free medical treatment for i inpatients, and corresponding grants are made toward the expenses incurred by patients receiving treatmen in private hospitals (the high quality of the servi available in the public hospitals of New Zealand is we known) The state mental hospitals give free treatmen to their patients All of these services are now finance by a part of the proceeds from the universal levy f Social Security

It remains true that the intended free general pra titioner medical benefits are only partially operativ because of the unwillingness of the New Zealand branc of the British Medical Association to cooperate But th measure of progress already made towards making New Zealand a reality of Social Security is fairly to borne in mind if we are to keep the whole picture perspective

In his letter of May 17, Dr Douglas Robb suggests unusual line of criticism For him, a large part of t trouble seems to be that the government have be dilatory in introducing a full cooperative system, th have been too respectful to the competitive basis practice among doctors, and Dr Robb's patience, seems, is almost exhausted Now, in the light of clear statements of policy made by the government, i not evident enough that if the medical profession of N Zealand would, in fact, prefer a national cooperati system of medical service, the government for th part would welcome such a proposal? But does t profession desire this, or is Dr Robb's merely the vo of one crying in the professional wilderness?

NEW ZEALANDER IN LONDO

Obituary

FRANCIS BERNARD CHAVASSE

M C, D M OXFD, M R C P, D O M S

Dr F B Chavasse, who was killed in a motor accident ar Warwick on July 5, was the third of the four sons Francis J. Chavasse, formerly bishop of Liverpool is brother Noel was one of the medical V C s of the st war, while Chavasse won his own M C in 1917 for his brave but fruitless efforts to find his youngest brother who was reported wounded and missing His only surviving brother was last year raised to the see of Rochester

Francis Bernard was born at Oxford in 1889, while his father was principal of Wycliffe Hall Like his brothers, he went to school at Liverpool College, and when he went up to Balliol in 1908 he showed the family turn for speed by winning the 100 yards in the freshmen's sports He also proved equal to his brothers' exacting academic standards, and in 1911 he was awarded Theodore Williams scholarships in anatomy and physiology and a Brackenbury exhibition Two years later he obtained a first class in the final honours school of natural science and returned to Liverpool to finish his medical studies at the university there He was an enthusiastic yachtsman and when the last war broke out he was away on a cruise He returned to finish his medical training at top speed, qualifying M R C S in 1915 He joined the R A M C. at once and served till the end of the war, first in the Dardanelles and later in France It was not till 1919 that he had leisure to take his B M and embark on the study of his chosen specialty A period of intensive work as clinical assistant at the Oxford Eye Hospital, at the eye department of the London Hospital and at Moorfields followed Soon after his return to Liverpool he was appointed to the special staff of the Eye and Ear Infirmary and the Royal Liverpool Children's Hospital He became lecturer in ophthalmology at the University in 1923

Chavasse was responsible for the seventh edition of Worth's Squint and he had also written important papers on orthoptic training and binocular vision Indeed one of his colleagues has described squint as the dream child of his brain His was a strong, thoughtful and thoroughly practical nature with an eager, forward-reaching mind crescive in its scientific curiosity and endeavour A fellow member of the Twenty Club recalls two papers of his which illustrated the natural balance in his character "One was a philosophical essay, probing deeply into human experience A few months later he gave us a paper on camping out, erecting a tent in his drawing-room, and showing to the smallest practical detail how to make a success of a camping holiday Both papers were entirely in character To his professional work he brought the same qualities of a sturdy, well-integrated personality "

JOHN SLIGHT GRAY

M B EDIN

Dr Gray was born in Edinburgh, and went to George Heriot's School where he secured a place in the rugby XV At Edinburgh University he played golf for the university team and was awarded his "green" Soon after his graduation in 1939 he went to the Coventry and Warwickshire Hospital as house-physician, later becoming senior resident in charge of the resuscitation wards and an assistant in a department of pathology Under the supervision of the director of the laboratories he also helped to develop the blood-transfusion service Dr Gray had been on duty during all the big raids on Coventry Earlier on the night of April 8–9 he was seriously injured in his left hand, but he refused to leave his wards A delayed action bomb exploded later and caused him further injuries which proved to be fatal

JOHN PATRICK GORE-GRIMES

M B DUBL

Dr Gore-Grimes, who was killed in the same raid as Dr Gray, was a native of Dublin He was educated at St Gerard's School, Bray, co Wicklow, where he became captain of the school in his last year He loved swimming and yachting and at Trinity College swam for the water polo team After his graduation in 1939, Dr Gore-Grimes held resident posts in Dublin and did post-graduate work at the Rotunda He came to England as house-surgeon at the Birmingham Children's Hospital, and last November moved to the Coventry and Warwickshire Hospital as resident for the senior physician He was keen, diligent and sincere and his untiring work on the night of April 8 will never be forgotten

IVOR McNEIL DRYSDALE

M B GLASG, SURGEON LIEUTENANT R N

Surgeon Lieutenant Ivor Drysdale, who has lost his life on active service was the son of Mrs Drysdale of Golfhill Drive, Glasgow He was educated at Glasgow High School, and at the University where he graduated M B in 1935 He was a member of the university O T C and an enthusiastic cricketer After qualifying he was for a time a houseman at Glasgow Royal Infirmary before entering the Royal Navy in 1936 For three years he served in stations in the Far East but since the beginning of the war he had been in home waters He was 29 years of age

JOHN ROSSLYN EARP

M A CAMB, M R C S, DR P H JOHNS HOPKINS

The death of Dr Rosslyn Earp on May 19 at his home in Delmar, New York, severs a transatlantic link Before qualifying from Cambridge and University College, London, during the last war he had served with an Anglo-Belgian ambulance and gained the Mons medal, the next five years he divided between relief work in France (where he had paratyphoid) and a hectic apprenticeship to medical journalism in London and Geneva, until the progress of a tuberculous lesion compelled attention and he elected to do his curing under Lawrason Brown at Saranac as he had been invited to direct the health department at Antioch College, Ohio Meantime he took his doctorate at Johns Hopkins and began a public health career which took him from Ohio to California and New Mexico and finally in 1937 to New York where he became director of the division of public health education and brought out weekly the official *Health News* All this while his lesion was growing on him, but he did not count it as a disability, praising rather the conservation of energy and time when he could summon committees to meet at his bedside Thus for 20 years of intermittent invalidism he retained the sanguine hopes of youth and was often able to bring them to pass And it was thus that the sphere of his influence developed from the discussion of adolescent problems at Antioch to the introduction of novel hygienic methods in a Western state, and finally to his advice being sought on large schemes of national health policy At 50 when he died his mind was still young

Rosslyn Earp was born in 1891 at Riber, near Matlock (his mother was daughter of Dr Decimus Hands), and went to Bridlington Grammar School where he was captain of the football XI Thence to St John's College, Cambridge, where he was a keen runner and had a cheerful singing voice His training for the medical O T C certificate turned him into a pacifist, but although a slave of conscience he loved his fellowmen and *phys Med* 1938, 1, 302) that superficial structures—e g, the tendinous origin of tensor fasciæ latæ and tendinous insertion of semi-membranosus-tendinosus muscles—often give rise to referred pain

In my experience pseudo-sciatica is caused by a muscular disease which can be located objectively in the myalgic spots I have discussed The muscles affected are tensor fasciæ latæ, gluteus medius and maximus, and sometimes quadratus lumborum Muscular sciatica can be cured in a short time by the injection of 1–2 c cm of 1% Procaine into each myalgic spot

Sciatica caused by a displaced intervertebral disc is very rare It must therefore appear surprising that 30% of his cases were referred by Kellgren to this source. I believe that a thorough examination for myalgic spots in the muscles mentioned above would have revealed that a number of these cases were of muscular origin This examination is simple and very worth while, since a positive result enables us to cure the patient without delay

M GOOD,
Lieut R.A M.C

PREMARITAL TESTS

SIR,—There are certain sections of Dr Violet Russell's excellent letter which call for further discussion She says that it is a pity to restrict the functions of a premarital clinic to the performance of Wassermann tests and suggests a short routine physical examination With this, I imagine, there will be general agreement but I feel I must join issue with her when she says that "For most couples no advice would be necessary and the doctor would only need to wish them luck"' One of the important tasks with which the medical profession will have to concern itself after the war is the stabilisation of the family unit, and the encouragement of parenthood Effective marriage preparation is an essential factor in the creation of a happy family life This involves a consideration of the following points

1 Physical health and freedom from venereal disease

2 Eugenic problems Many couples are uncertain as to whether there are elements in their family history which should preclude them from having children

3 Sterility Whilst the investigation of this condition in the woman requires procedures which should not be undertaken at this time, it is often possible during a routine examination to discover conditions which indicate the possibility of there being some degree of infertility—which it may or may not be advisable to deal with at that time, but about which the patient can certainly be warned In particular is it necessary to point out that if conception has not occurred after a year's trial the condition should be investigated and not "left to nature" A man's fertility can of course be assessed much more easily It is often advisable to do this and indeed the request for such an examination is often made spontaneously by the man

4 Every woman should be examined before marriage to make sure that the hymen will not interfere with normal and easy coitus and every man to see that he possesses no physical handicap

5 Much helpful advice may be given regarding technique and the importance of ensuring mutual orgasm This is a matter about which the public is lamentably ignorant

6 Children The need for a couple to prove their fertility early should be stressed and some indication can be given of the sociological implications of marriage and the valuable psychological factors that are involved in the acceptance of the responsibilities of parenthood by both partners

7 Family spacing This involves a correct understanding of the positive use of contraceptives and the danger of their misuse All couples want help on this matter and it is of paramount importance that the medical profession should concern itself with this problem and be in a position to provide young people with constructive principles upon which their married lives should be based In an ideal society contraception would be sought from, and provided by, doctors either privately or in clinics Indeed the rightful place for the carrying out of all this premarital work is in the welfare clinics, whose functions should be extended to cover this field Laboratory help, expert knowledge and time are essential

8 Many psychological problems arise and can receive appropriate attention

These few examples must suffice to show the scope and interest in the whole problem of premarital examination and education In other countries, notably Scandinavia and America, the need for this type of advice is b recognised and more effectively provided

In order to complete the picture, it is necessary t point out that premarital instruction should be the last phase in a carefully thought out educational system provided for the whole population and embracing home school and college Such a policy, based upon biological and psychological principles, should be designed to show that sex is a positive factor in life having widespread personal and social implications which must be properly understood and respected before the individual can hope to reach a fully balanced maturity This should go hand in hand with a more widespread system of practical instruction in the art of family management and the care of children together with the abolition of those economic conditions which are militating against parenthood

Harley Street, W 1 EDWARD F GRIFFITH

"INGROWING TOENAIL"

SIR,—While recognising that space did not give Mr Nuttall room for elaboration, I feel I must protest against the undue simplification of the ætiology of chronic lateral paronychiæ of the great toe The undue proportion of bilateral cases (by this I refer to both feet, and not to both sides of the nail, conveniently called "double") is not entirely due to tight shoes Examination of such cases frequently shows the presence of one of two conditions, either ugly flat toenails often ridged and often present on the opposite uninvolved foot in unilateral cases, or unusually long great toes which have led to undue pressure on the shoe It is surprising how often both these conditions will prove to be a family idiosyncrasy, I have looked after one family in which the father, two sons and a daughter have all lost their nail beds for recurrent paronychiæ As Mr Nuttall mentions the name "ingrowing toenail" should be abolished, for it gives a quite erroneous idea of the pathology The most common primary cause is neglect of foot cleanliness, with a subsequent subacute lateral paronychia This may be started by the wearing of one pair of tight shoes The persistent hyperæmia of the lateral side of the nail bed results in uneven growth of the nail, shown by longitudinal ridging and flattening of the nail, so that the nail fold no longer has a smooth rounded surface to overhang Removal of the nail or improvement of the footwear seldom results in a cure as the nail bed continues its irregular growth, and this is shown by the disappointing results from simple removal of the nail

It will be seen that the operation suggested though useful in some cases is unsuitable for those with an excessively long first toe, when the shortening of the toe by the removal of the nail bed and part of the terminal phalanx is preferable In spite of Mr Nuttall's contempt for sepsis I feel that it is wiser to clean up the paronychia before doing the radical cure In the long run it saves time as neither operation should lead to much invalidism

I should like to thank Mr Nuttall for the dodge of using towel forceps to steady the toes With the smaller toes this should be even more of an advantage

Hammersmith, W 6 J G BONNIN

SACCHARIN SHORTAGE

SIR,—Many of my diabetic patients are unable to obtain saccharin tablets from their local chemists, whereas some of my non-diabetic friends are able to do so Can some remedy be brought into play to overcome this?

Chelford, Cheshire E S EVANS

*** Diabetics should arrange with their regular chemists to reserve supplies for them, where there is difficulty they can be assured of preference if they present a note from their doctor —ED L

FOOD POISONING —The alarming outbreak of gastro enteritis which occurred on Thursday of last week among civil servants at Berkeley Square House has been traced to minced meat, the symptoms being probably due to preformed toxin rather than bacterial infection Some 60 victims taken to St George's and Westminster Hospitals have now returned to work

Morgan —On July 23, at Clevedon Hugh Brooming Taylor Morgan M D Edin, of Cosham Portsmouth, aged 74

Robinson —On July 26 in London, Harry Robinson, O B E, F R C S

Webber —On July 25 Leonard Mortis Webber, M R C.S D P.M medical superintendent of Netherne Hospital, Surrey aged 55 this love was returned with interest in whatever grouping he met them His help in this office at a very lean period was welcome and was followed by a few months of intensive work on *Tubercle* in its first year of publication His writing was a development of the epistolary style, easy and natural, and he found no occasion to develop mannerisms Some unsigned letters in our columns have set out vividly one side of the chief medico-political problem in U S A of the last decade He married Kathleen M Goodliffe of Nottingham and leaves her with four children

WILLIAM HANNA

M D BELF , D P H

Dr Hanna, who died on July 13, was for more than 30 years attached to the Liverpool health service After taking his M A degree at the R U I in 1893 and qualifying in medicine two years later, his professional bent towards the prevention of disease led him to a junior post on the staff of Dr A K Chalmers, then M O H of Glasgow, and then to the government laboratory service in Bombay where he took full advantage of his opportunities to study plague and other tropical diseases and the methods for their suppression When the rapidly developing sanitary service of the Port of Liverpool called for additional staff his knowledge and experience marked him for appointment In Liverpool he found full scope, making many suggestions for administrative improvement and the betterment of the conditions, appliances, and sanitation on board ship which were adopted by owners and port authorities and set a standard for the Board of Trade Seamen everywhere owe to him a large measure of their health, comfort and safety When in 1923 he succeeded Dr A A Musson as deputy M O of the port he became largely responsible for the purity of the city's food-supply His authority on smallpox was unchallenged and his textbook on the subject had a world-wide circulation He also collaborated with Hope and Stallybrass in a monograph of industrial hygiene Moreover as university lecturer in public health administration he helped students to a broad view of state medicine But his disposition was not of a kind which readily acquires a large area of acquaintances , he was reserved and showed a diffidence almost amounting to shyness He was a faithful and devoted public servant and his firmest friends were amongst those who knew him best

Public Health

From the Annual Reports

MIDDLESEX

BECAUSE of the death of Dr John Tate in April, 1940, the 1938 report for Middlesex was not published until April, 1941 As Dr Macaulay, the present M O says, it is now of value more as a record than for information The race of industry to the North which started roughly a century ago was reversed after the last war That the shift was not accompanied by the disasters of the industrial revolution is the best certificate of merit which our public hygiene has received It shows not only that we have learned how to make industry comparatively healthy but that we had gained from the powers controlling it help in applying our knowledge At the 1921 census the population of Middlesex was 1,253,002 , in 1938 it was estimated at 2,058,300 , during that year the population increased by 43,800, of which 12,937 came by natural means and 30,863 by immigration The immigration figures are lower by 50% than those of the previous year and suggest " a check in the flow of population into Middlesex " A population which has been doubled in 20 years, in spite of a birth-rate which had been rapidly falling until near the end of the period, must of necessity be more a collection of persons than a true community, so the vital statistics of Middlesex are not comparable with those of settled counties Since 1934 the birth-rate has risen steadily from 14 6 to 15 4, but in view of the nature of the population the slightness of this rise denotes a fall in fertility There are no county boroughs in Middlesex, so the administrative corresponds with the geographical—or rather historical—county In 1938 there were 31,617 births and 18,680 deaths The bu rate varied in the urban districts from 25 in Felth to 11 4 in Southgate and the recorded death-rates fr 11 3 in Sunbury and Hornsey to 6 6 in Potters B The comparability factor varies from 1 36 for Hayes a Harlington to 0 91 for Hornsey, and shifts the high comparable death-rate to 11 9 in Tottenham but lea Potters Bar with the laurels at 6 9 Infant mortal varied from 59 in Hayes and Harlington to 31 Southgate, the average for the county being 4 Of the 18,680 deaths only 9184 were of persons over More than half as many (4813) were in persons a 45–65 and 2873 in persons aged 15–45 In a populat of standard composition this would be a bad record spite of the crude death-rate being 9 1, which co parability raises only to 9 7 against the England a Wales rate of 11 6 The area of Middlesex is 148, acres and its density therefore 13 8 , it has really cea to be a county and like London is a vast urban ar Much of Middlesex has been part of the metropolis many years and the population of these districts h not increased to any extent , that of Tottenham h actually fallen since 1921 The change is in those par which used to be rural , thus, the population of Wembl increased from 18,239 in 1921 to 118,800 in 1938

WARWICKSHIRE

Dealing with the increased prevalence of scabie Dr Hamilton Wood says that this has been the princip cause requiring admission of evacuees to sick bay He says it is often contracted from parents or relativ coming from evacuable areas on visits The increas in detected scabies started nearly two years before th war and was fairly generalised Its increase has bee more rapid since evacuation and has spread to distric from which it had been absent for many years Th incidence of scabies in the general population is unknow but judging from the records of school medical inspecti it appears to have been slight before 1937, even in crowded parts of great cities It is difficult to see w the acarus should have extended its range before war, but easy enough to explain why it has done so si Among 21,612 children examined in Warwickshire cases of scabies were discovered in 1939, more t twice as many as in 1938 Dr Wood says that inst tional treatment of scabies is successful, but domicil treatment protracted and not always satisfact There were no cleansing stations in the county last y

Infectious Disease in England and Wales

WEEK ENDED JULY 19

Notifications —The following cases of infectious dis were notified during the week smallpox, 0 , sca fever, 718 , whooping-cough, 4662 , diphtheria, 8 paratyphoid, 329 , typhoid, 44 , measles (exclu rubella), 4610 , pneumonia (primary or influenzal), 5 puerperal pyrexia, 132 , cerebrospinal fever, 1 poliomyelitis, 10 , polio-encephalitis, 4 , encepha lethargica, 2 , dysentery, 85 , ophthalmia neonator 88 No case of cholera, plague or typhus fever notified during the week

Of the 329 cases of paratyphoid 44 were reported from county of Chester (Birkenhead 10, Bebington 13) , 179 Lancaster (Bootle 17, Liverpool 78, Manchester 16, St Helens Of the 44 cases of typhoid 12 scattered cases were also reported Lancaster Smaller aggregations of paratyphoid were rep from Northants (Brixworth 14) and Staffs (Stoke 5)

The number of civilian and service sick in the Infectious Hos of the London County Council on July 16 was 1377 , inclu scarlet fever, 121 , diphtheria 234 measles 144 , whooping co 535 , enteritis 18 chicken pox 45 , erysipelas, 40 , mump poliomyelitis, 1 , dysentery 1 cerebrospinal fever, 30 puer sepsis, 10 , enteric fevers, 19 german measles, 5 , other dis (non infectious), 74 , not yet diagnosed, 83

Deaths —In 126 great towns there were no deaths f scarlet fever, 6 (0) from enteric fever, 24 (2) f whooping-cough, 3 (1) from measles, 19 (0) from d theria, 35 (1) from diarrhœa and enteritis under 2 ye and 4 (0) from influenza The figures in parentheses those for London itself

Edmonton Chester, Crosby, Liverpool, Manchester, and Sw each reported 1 fatal case of enteric fever Manchester and She each reported 3 deaths from whooping cough

The number of stillbirths notified during the week 187 (corresponding to a rate of 39 per thousand t births), including 9 in London

Notes, Comments and Abstracts

MATERNITY IN WAR-TIME

In his postscript to the nine-o'clock news on July 15 Mr Ernest Brown said that over 25,000 babies had now been born in our ninety war maternity homes The reception of these young citizens is an important piece of civil defence and it is interesting to learn from Dr A Leslie Banks and Dr L G Norman, medical officers of the Ministry of Health, how the scheme works in their region [1] Under the threat of bombing at the beginning of the war 1900 mothers in the last month of pregnancy were evacuated into the area and a hundred maternity units with 1385 beds were hastily established to receive them But no bombs came, and during the early months of 1910 only six homes with 227 beds were in use When the real thing began the evacuation of expectant mothers increased, and other homes which had been retained on a care-and-maintenance order were reopened, until by last November the region had twenty-three homes with 673 beds and by the end of the year 5439 mothers had been confined in them

This war-time organisation has been skilfully and economically grafted on to the peace-time services of the region Each county and county borough M O H was put in charge of the administration of the homes in his area the antenatal care of the mothers was put under the welfare authorities, and arrangements with obstetric consultants extended To avoid overcrowding the regional office retains control of the distribution of the mothers who register with their local M O H or through the L C C Only cases which are expected to be normal are sent to the homes—complicated cases go to a hospital in the area or to a central home where a consultation is available—and the confinements are conducted by midwives, who give gas-and-air if they are qualified to do so Homes with over 40 beds have a resident medical officer A matron or sister is in charge of the smaller homes A local doctor may be summoned if need be and either a member of the county medical staff or a local practitioner has general supervision of the home Medical students are taught at some of the homes which are staffed by London teaching hospitals and there is a similar arrangement for pupil midwives It has been difficult to find enough midwives to run the homes and only cooperation of the Central Midwives Board has made it possible to maintain adequate staffs

Many of the homes are housed in large private houses, which were requisitioned Extra bathrooms, water-closets sinks and sluices had often to be installed, but as few alterations as possible were carried out Though all the homes were in reception areas it was found necessary to provide air-raid protection The sizes of the homes vary from 15 to 100 beds arranged in 4–6 bed wards, and a floor-space of at least 96 sq ft is allowed for each patient There is one labour bed to 10 lying-in beds, one midwife to 4 patients, one assistant nurse to every 22 patients; and one domestic servant to every 3 patients Each home has an isolation room where cases of puerperal pyrexia are placed for observation Septic cases are transferred to an isolation hospital In each home there is also a day room for up-cases, a nursery for the babies, while a bathroom is often used as a reception-room where patients are examined Ingenuity and goodwill have reduced costly equipment to a minimum. But though instruments can be sterilised in a fish kettle, dressings are more difficult and where possible they are supplied in drums from a neighbouring hospital In isolated homes in the early days they were sometimes baked in biscuit tins, but gas or electric autoclaves were installed as soon as possible Other semi-domestic problems which were solved by individual resource were alternative emergency lighting in labour rooms, adequate exits for stretcher patients in case of need, and disinfection of the inevitable bedpans

To begin with, the mothers were billeted near the homes before and after their confinements But as accommodation grew scarcer the need for hostels became clear to the billeting authorities, who indeed sometimes set them up themselves The welfare authorities have now taken over both antenatal and postnatal hostels (Mr Brown said there were sixty of these in the country), and they have proved them worth The hostels are run on communal lines and the mothers do the light work themselves A midwife is in charge of the antenatal hostels and in the postnatal hostels the staff is experienced in infant care

A SCIENTIST'S NEW ORDER

If a book is a great book when it says today what a multitude will be saying tomorrow, when it clearly verbalises thoughts that with most people are only whispering guesses, then the little Pelican book, "The Scientific Attitude," by C H Waddington, Sc D, a Cambridge zoologist of 36, is a great book indeed Not that it couldn't be better, the chapters on art, for instance seem to take inordinate space Not that it couldn't have been written by somebody else, for almost any young scientist could write a similar book and let's hope many will But it does far more than describe an attitude, it holds up an ideal, it gives a creed which in these days of shifting values looks solid and unsmirched This is a book not about Science the hired assassin or protector of the state, the mechanic of industry, the servant of big business the sanitary technician who kills or keeps the fungoid foes of man at bay, but Science with an ideal that is all the better for being minutely dissected, with a conscience which is the more vigorous for being analysed, with a mission and a questing way of life that seeks control Here is a creed that exalts the last formed and most highly developed faculty of man, a tested creed in lesser fields, an exciting, gripping creed to which youth can turn and not in vain, to which millions in fact are starting to turn, to which millions more will turn when unbridled by Sam Browne belts and instant duty It does not make the mistake of wanting to form a party, a collection of men and women who always seem to revert to the jealous and egotistical interplay of tribal life with the lowest common denominator output, but to put into universal currency a set of ideas, like fresh air breaking through poison gas, a spirit

If you are satisfied with things as they are, if you think that business men and lawyers and politicians have done well with this last quarter century, don't buy this book, it might upset you, but if you believe that humanity can rise above the entertainment of world wars, above the mass stupidity of world slumps, above the squirrel hoarding of personal possessions, the protective groupings and hounding of monopolies, the unanalysed bondage of loyalties, then plank your sixpence down like a man and take comfort A revolution? Certainly, of thought, but the decrees of which would be of such mildness as to ask that anyone who aspires to govern shall have a scientific training, that anyone who would be priest or teacher shall have a summary of what is known of the forming and working of man's body and mind The writer has little good to say of nazi-ism or communism, but praises other activities of the Soviet which, starting from an incredible scratch, have spent more money on science than any nation at any time, in whose towns "well-stocked scientific technical bookshops are as common as tobacconists in London"

SCRUPULOUS SATELLITES

The Board of Registration of Medical Auxiliaries have lately published the third edition of their register of chiropodists and the second edition of their register of orthoptists The register of chiropodists contains the names of members of four qualifying bodies whose standards of curriculum and examination have been approved by the board the Incorporated Society of Chiropodists the British Association of Chiropodists, the Chelsea Chiropodists Association, and the Northern Chiropodists Association The qualifying body for orthoptists is the British Orthoptic Society The board also maintains registers of physiotherapists (including masseurs, radiographers, and biophysical assistants) and of dispensing opticians Medical practitioners, hospital and local authorities may obtain copies of these registers free on application to the secretary of the board, B M A House, Tavistock Square, London, W C 1

Surgeon Rear-Admiral G F Syms, F R C S, R N, has been appointed an honorary surgeon to the King

A STUDY OF THE PATHOGENESIS OF THYROTOXICOSIS*

F F Rundle, M B Sydney, F R C S
RGICAL CHIEF ASSISTANT WESTMINSTER HOSPITAL, CLINICAL RESEARCH WORKER L C C THYROID CLINIC, SURGEON, E M S

Aristotle said " let us understand the facts then we may seek the cause " In thyrotoxicosis we are still in process of collecting and trying to understand the facts Thus any study of its pathogenesis is as much an inquiry into the nature of the disease as into its causation In fact one of the greatest difficulties is to form an adequate concept of the syndrome

COMPONENTS OF THYROTOXICOSIS

The central disorder in thyrotoxicosis is some degree of thyroid hyperactivity Other more or less independent components are the ocular changes and a group of nervous manifestations, termed by Rasmussen (1937) " the psychoneurotic syndrome " While of course some degree of thyroid intoxication is essential for the diagnosis, the ocular and nervous components are inconstant and unessential It is even doubtful whether the nervous phenomena form an integral or characteristic part of the disease

The thyroid intoxication—Harington and his co-workers (1935) have established the fundamental fact that the glandular secretion in thyrotoxicosis, though excessive in amount, is not qualitatively different from normal This has greatly clarified the pathology of the disease, the elaborate dysthyroidism theory of Plummer being rendered invalid Incidentally proof was provided of the wisdom of Aristotle's injunction But the precise nature of the definitive secretion of the thyroid is unknown, nor can the amount of hormone passing into the circulation be measured directly either in health or disease Moreover, indirect methods of measuring the degree of thyroid intoxication, such as the basal metabolic rate, are not wholly reliable Hence the expression " thyroid intoxication " cannot have an exact meaning

The ocular component—It is significant that the ocular component and the thyroid intoxication, though usually associated, may occur as independent phenomena Thus in 332 consecutive cases of thyrotoxicosis there was lid-retraction or proptosis or both in about 3 patients out of 4 But cases in which the ocular signs are present without goitre or hypermetabolism are not very rare

Case 1—A married woman aged 48 Her father and a paternal cousin had both had thyrotoxicosis She complained of " a bad eye ", the left eye had been staring and watered when out of doors or in a wind for the past 3 months There was no pain or diplopia and no symptoms of general disease She was well nourished There were no abnormal physical signs save in the left eye which showed retraction of the upper lid identical with that in Graves's disease There was no clear exophthalmos (exophthalmometer reading 15 mm for both eyes) or ophthalmoplegia The basal metabolic rate and the galactose index were normal

Here typical lid-retraction occurred in the absence of goitre and hypermetabolism The family history is significant Such cases may retrogress, remain stationary for months or years, or, more usually, progress to typical exophthalmic goitre Where, as in this example, thyroid intoxication does not develop, the case is perhaps best regarded as an abortive form of Graves's disease in which the thyroid epithelium has not responded to the causal stimulus Clearly cases in which only the ocular component is present provide very strong evidence to support an extrathyroid theory of origin There is, indeed, powerful evidence that the thyroid intoxication is not the cause of the eye changes On the one hand, typical lid-retraction and proptosis may develop in patients without goitre or hypermetabolism, or exophthalmos may appear for the first time or increase after thyroidectomy (it is significant that postoperative hypothyroidism is often present in these cases) On the other hand eye signs may be absent when the thyroid toxæmia is very severe, and Smelser (1938) states that thyroxine therapy in guineapigs reduces the weight of the retrobulbar contents and causes enophthalmos

The clinical evidence that the ocular changes have an extrathyroid origin supports the pituitary theory of Graves's disease But experimental data provide the most suggestive evidence Extracts of anterior lobe not only activate the thyroid gland and cause secondarily all the manifestations of thyrotoxicity but also result in exophthalmos Some of the clinical factors associated with the onset of thyrotoxicosis appear to act by disturbing the higher controlling mechanism of the gland But there is evidence also that the responsiveness of the thyroid epithelium is variable Certain thyroid conditions, notably simple goitre, may predispose to the thyroid intoxication of Graves's disease It is therefore convenient to speak of pituitary and thyroid factors in the pathogenesis

SIGNIFICANCE OF EXOPHTHALMIC OPHTHALMOPLEGIA

It is instructive to consider a group of patients to which Brain (1938) has given the name " exophthalmic ophthalmoplegia " Severe proptosis and ophthalmoplegia usually dominate the clinical picture The cases fall into three main groups, of which the following are examples

Case 2—Postoperative type A woman aged 49 (fig 1) Subtotal thyroidectomy for severe thyrotoxicosis with exophthalmos in September, 1937 Diplopia and epiphora first noticed 12 months afterwards She then had about 7 mm of proptosis on both sides and marked weakness of both external recti Postoperative hypothyroidism was present

Case 3—Coexistent with active thyrotoxicosis A man aged 59 (fig 2) Severe thyrotoxicosis of some 8 months' duration Loss of weight (2½ st) in spite of excessive appetite Basal metabolic rate + 46% Both eyes proptosed (exophthalmometer readings, R 24 mm , L 23 mm) Severe chemosis Gross limitation of upwards, downwards and outwards movement of both eyes Thyroidectomy relieved the thyroid intoxication but left the eyes unchanged

Case 4—Without goitre or hypermetabolism A man aged 61 (fig 3) Complained of prominence of L eye and double vision The R eye was normal but L eye was proptosed (exophthalmometer reading R 15 mm , L 19 5 mm), much retraction of L upper lid , elevation, abduction and adduction of the globe were grossly limited. No goitre or signs of thyrotoxicity Basal metabolic rate + 12%

Relevant data from 15 cases of exophthalmic ophthalmoplegia are given below

Exophthalmic ophthalmoplegia occurred—

(*a*)	postoperatively in	7	cases *
	with thyrotoxicosis in	5	,,
	without goitre or hypermetabolism in	3	,,
(*b*)	with lid retraction in	10	
	with proptosis in	15	,,

Mean exophthalmometer readings in—

20 ophthalmoplegic eyes	23 ± 2 8 mm
146 exophthalmic eyes without ophthalmoplegia	18 ± 1 72 mm
276 normal eyes	14 5 ± 2 5 mm.

* 4 had hypothyroidism

Lid-retraction and proptosis in exophthalmic ophthalmoplegia seem to differ from these signs in Graves's disease in degree but not in kind This is suggested strongly by cases of progressive postoperative exophthalmos which develop ophthalmoplegia It is significant that lid-retraction identical with that in Graves's disease occurred in two-thirds of the cases Despite some overlapping of the values in individual cases there is a clear general relationship between the severer degrees of proptosis and the incidence of ophthalmoplegia

Turning to the metabolism, exophthalmic ophthalmoplegia developed after thyroidectomy or with active thyrotoxicity in 12 of the 15 cases Either combination emphasises the intimate connexion between exophthalmic ophthalmoplegia and the syndrome of thyrotoxicosis Moreover in all 3 cases without goitre or hypermetabolism this relationship was revealed by the presence of characteristic lid-retraction In one of this group the family history provided suggestive evidence ;

* A Hunterian lecture delivered before the Royal College of Surgeons of England on Feb 10 1941

her only sister and her mother were goitrous and on the maternal side 2 aunts and an uncle had goitres

An attractive hypothesis is that these cases represent abortive forms of Graves's disease in which the thyroid epithelium has failed to respond to the stimulus commonly causing both exophthalmos and thyroid intoxication There is comparable evidence that in certain people the thyroid epithelium shows an extraordinary resistance to anterior-pituitary extracts Sharpey-Schafer and Schrire (1939) found that small doses of thyrotropic extract regularly cause thyroid enlargement, tachycardia elevation of the basal metabolic rate and creatinuria in normal human subjects In most cases of hypothyroidism the injections restored the metabolism to normal, but in some cases of hypothyroidism even massive doses failed to evoke a response, and biopsy of the thyroid isthmus in one such case showed appearances within normal limits We may conclude that the responsiveness of the thyroid epithelium is variable Hence it is possible that a pathological lack of responsiveness may account for the occurrence of exophthalmic ophthalmoplegia without goitre or raised metabolic rate

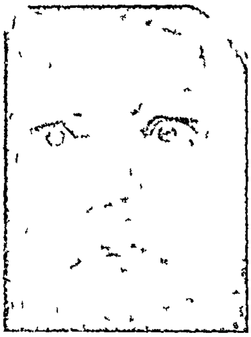

FIG 1—Postoperative exophthalmic ophthalmoplegia Both external recti are affected

The term exophthalmic ophthalmoplegia is a useful one since it indicates the usual association of considerable exophthalmos with the muscular palsy Brain (1938) claims that exophthalmic ophthalmoplegia is a syndrome clearly distinguishable from exophthalmic goitre But the evidence here presented suggests that even when exophthalmic ophthalmoplegia is present without thyrotoxicity the condition is best regarded as an extension of the thyrotoxic syndrome and not as sharply distinct from it It seems desirable to use the term simply to denote a particular combination of eye signs occurring alone, in conjunction with active thyrotoxicosis or as a complication after thyroidectomy Incidentally, since the behaviour of the ocular and thyroid components of thyrotoxicosis is more or less independent, the state of both must be specified if the diagnosis is to be clear and adequate

It will be seen also that exophthalmic ophthalmoplegia was associated with a normal or subnormal metabolic rate in two-thirds of the cases, and there is a suggestive comparison between this clinical group and certain experimental data Smelser (1937) found that gross proptosis followed the injection of anterior pituitary extracts in thyroidectomised but not in intact guineapigs He claimed that an increased bulk of the retrobulbar contents of the orbit caused the proptosis and was due to œdema of the tissues But the difficulty of arguing from results in the experimental animal to disease states in man is shown by the fact that the only case of exophthalmic ophthalmoplegia in the present series which came to autopsy showed no œdema of the orbital fat when examined histologically

ANTECEDENT GOITRE

The importance of the thyroid factor in pathogenesis is suggested by the frequent development of thyrotoxicosis in patients already suffering from simple goitre It is suggestive that this secondary toxic goitre is fairly common even among city-dwellers Thus after excluding a small group of patients from an endemic area, 62 cases, or about 1 in 5 of the present series, gave a history of antecedent goitre Usually the previous goitre had appeared at puberty or during adolescence Sometimes it had subsided in adult life but the subsequent development of thyrotoxicosis indicated that the gland remained a locus minoris resistentiæ

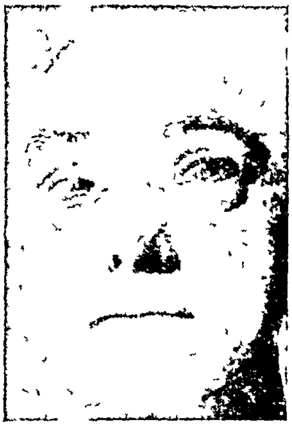

FIG 2—Exophthalmic ophthalmoplegia associated with severe thyroid intoxication Note chemosis and limited abduction of the left eye (photograph taken soon after thyroidectomy)

There is also powerful evidence from goitre maps endemic goitre predisposes to thyrotoxicosis M don (1936) in the United States, McEwan (1938) in country and Wyndham (1940) in New South Wales made geographical surveys of the incidence of simple toxic goitre Each author found that the areas of h est incidence of thyrotoxicosis coincided with those highest endemicity And, as is well known, exopht mos is not common in secondary toxic goitre, the intoxication being usually the sole manifestation observation may mean that the presence of simple goit predisposes more particularly to this component of t thyrotoxic syndrome

In this connexion, an interesting experiment w described by Anderson and Collip (1934) A group rats suffering from spontaneous goitre was injected wi the same dose of thyrotropic pituitary extract as a gro of control rats The goitrous rats we much more susceptible, and responded b developing a hyperacute form of experimental thyrotoxicosis In one, the basal metabolism reached 262% of normal compared with an average of 120–130% for the controls Such a result is highly suggestive, but it should be noted that Remington (1937), working with rats in which goitre had been induced experimentally, was unable to obt confirmatory results In his experime the goitrous rats showed no increased susceptibility

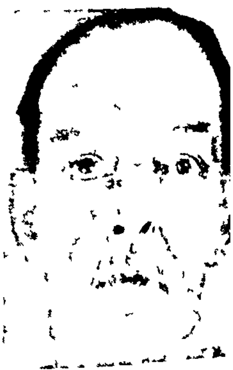

FIG 3—Exophthalmic o thalmoplegia of the eye without goitre or hy metabolism Note c siderable lid retraction

HEREDITY

The evidence that goitre arises as an heredit characteristic in certain families is strong In this ser of 332 patients, 72 (22%) gave a family history of thr disease Different forms of thyroid disease occurr simple goitre predominating (see table) Hence it is thyrotoxicosis specifically but rather the defect thyroid stock that is inherited

The main facts concerning the hereditary aspect thyrotoxicosis can be shown by representative cases

Family A—This family tree shows the goitrous diath in 3 successive generations (fig 4) Thyroid weakness sh itself irregularly as simple or toxic goit Here it is transmitted through femal but transmission through males does occ Moreover, demonstrated this family, goi is neither tra mitted as simple Mendel dominant nor a simple rec sive, if it wer Mendelian do mant, all the c dren in t second and th generations would be affected Moreover, it cannot b Mendelian recessive since goitre is present in both the mot and her children, even though the latter are heterozygous is suggested that some other unit character which predisp to goitre is transmitted with the genes and in suitable circ stances goitre or thyrotoxicosis develops

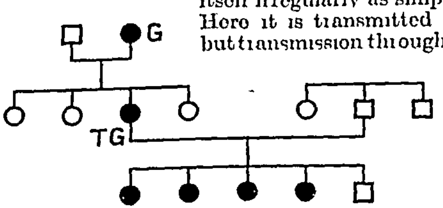

FIG 4—Family A Squares represent males, circles females, those with thyroid disease shown in black G = goitre, TG = toxic goitre, H = hypothyroidism, M = myxœdema

Family B—This tree shows a particularly heavy incide of different types of thyroid disease in the same family (fig There were 2 members with toxic goitre, a third with m ma and a fourth with hypothyroidism One of those with ves's disease had 2 daughters, the younger of whom eloped a simple goitre in adolescence There was a strong sical re- mblance tween the other and r goitrous ughter on e one hand, d the father and the non goitrous daughter on the other ere the constitutional factor stood out clearly

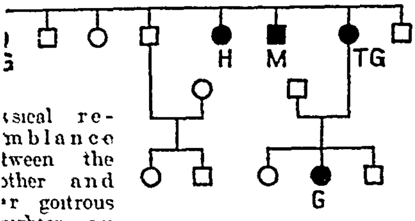

FIG 5—Family B

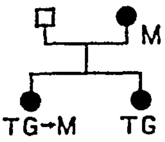

FIG 6—Family C

Family C—In this tree (fig 6) there is a myxœdematous other and twin daughters, one of whom had exophthalmic oitre which remitted under iodine therapy Typical myx-edema then gradually supervened A few years later the cond twin developed exophthalmic goitre She has now een observed for 3 years and without any treatment has ndergone a complete remission Because of their similar ehaviour the possibility arises that the two are uniovular twins

AMILY HISTORY OF THYROID DISEASE IN 322 THYROTOXIC PATIENTS AND 218 NORMAL CONTROLS

Thyroid disease in family	No of families affected	Incidence (%)
hyrotoxic patients—		
imple goitre and/or thyrotoxicosis and/or myxœdema	72	22
Simple goitre	50	15 5
Thyrotoxicosis	32	10
Myxœdema	5	1 6
ontrols—		
Simple and/or toxic goitre	12	5 5

All 3 subjects—the mother and her 2 daughters—belong to the same blood group, group B Incidentally these cases illustrate the type of Graves's disease which remits spontaneously or, without operation, gives place to myxœdema

PSYCHIC TRAUMA

It is an intriguing fact that psychic trauma is associated with the onset of symptoms in a comparatively high percentage of cases Marañon (1921) emphasises that they often volunteer the information that some major shock worry or stress seemed to bring on the illness In the present series, 42% of patients associated psychic trauma with the onset, and this figure agrees with that from other studies (Eason 1927, Gardiner-Hill 1929)

CASE 5—A man aged 53 with severe thyrotoxicosis There was a goitrous family history I questioned him closely about the possibility of worry, stress, infection or other factor contributing to the onset of his illness, but he denied all knowledge of any such cause Later he came into hospital when I again questioned him with the same result He responded well to rest and iodine Thyroidectomy was done He made a good recovery but considerable restlessness, tremor and flushing persisted A mild anxiety state was present Again I questioned him about possible worries with his work or amily I asked him whether there might not be some lifficulty in his relations with his wife It then came out that ome 3½ years before his wife had had a hysterectomy done for ancer and that he had not had intercourse with her since He had remained continent for 3 years but then began having egular intercourse with a married woman living nearby. Her husband was on night shift and the patient paid his visits fter he had left for work The constant fear that they would e discovered and that his family and the neighbours would earn of the affair gradually "got him down" He became so haky and nervous that eventually he had to give up his work

His case points two lessons first that such a cause of major emotional stress may remain concealed unless erreted out, secondly that a mild anxiety state may persist after thyroidectomy unless the mental difficulties are adjusted concurrently with other treatment In this patient the anxiety state was mild, but psychoneurosis may assume major proportions as in the following case

CASE 6—A young Dutch girl who had come to London to marry an Englishman she had met in Amsterdam He wrote one day to say that he was already married and had a family She was very depressed and said that for weeks she cried every night and could not sleep She did not want to return to Amsterdam and took a post in London, but she became more and more depressed She noticed a lump in her neck The symptoms of both hysteria and thyrotoxicosis developed She began to feel that she was all alone in the world and that everyone was against her The notes from a psychiatric clinic state that "she is depressed, tearful and sleepless, feels that life is not worth living and has suicidal thoughts" She presented the signs of severe Graves's disease but her case was overlaid with hysterical symptoms and depression After suitable preparation thyroidectomy was done and her physical condition improved rapidly, but the mental depression and hysteria persisted for many months Gradually, however, she became more cheerful as she realised that she had really had a lucky escape

When neurotic disorder coexists with thyrotoxicosis it is nearly always found that psychic trauma is a prominent factor in the onset of symptoms It thus seems possible that thyrotoxicosis and psychoneurosis have the factor of mental stress in common at their origins But whatever rôle psychic trauma has in the pathogenesis of Graves's disease, there can be no doubt that a sudden shock may greatly aggravate the disease when already present Thus a sudden shock has often been followed within a few hours or days by the full-blown picture of thyrotoxicosis, and, though it has generally been agreed that the disease must have already been present in latent form, it seems clear that psychic processes can modify thyroid activity But their modus operandi in doing so is unknown Here then is a problem in psychosomatic relations involving the question of the central representation of the thyroid and possibly also of the anterior lobe of the pituitary

ONSET AT SEXUAL EPOCHS

The frequent development of thyrotoxicosis in relation to one or other of the sexual epochs strongly emphasises the relationship between the thyroid and female sexual function The menopause was the epoch most commonly inculpated, for a fifth of all the cases developed within 2 years of it This is shown by the preponderance of patients of this age-group in the distribution curve (fig 7) The anterior lobe of the pituitary is, of course, closely concerned with the regulation of female sexual function There is evidence that after castration the urinary excretion of gonadotropic factor rises (Rowlands and Sharpey-Schafer 1940) It is possible that the close linkage between the gonadotropic and thyrotropic functions of the anterior lobe results, in certain cases, in a concomitant increase in these secretions after the menopause or at other epochs in the female

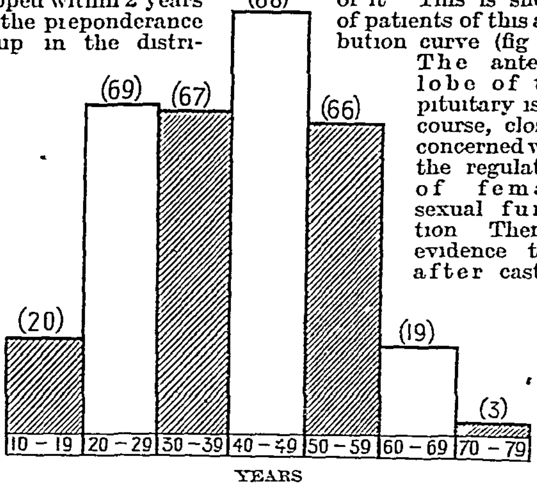

FIG 7—Age distribution in 332 patients with thyrotoxicosis (number in each age group is shown in parentheses)

If in patients with thyrotoxicosis we could demonstrate an abnormally high thyrotropic hormone content of the blood, it would be powerful direct evidence to support the pituitary theory of origin of the disease But studies of the blood have mostly given negative results (Fellinger 1936, Hertz and Oastler 1936, Cope 1938) and doubt has her only sister and her mother were goitrous and on the maternal side 2 aunts and an uncle had goitres

An attractive hypothesis is that these cases represent abortive forms of Graves's disease in which the thyroid epithelium has failed to respond to the stimulus commonly causing both exophthalmos and thyroid intoxication There is comparable evidence that in certain people the thyroid epithelium shows an extraordinary resistance to anterior-pituitary extracts Sharpey-Schafer and Schrire (1939) found that small doses of thyrotropic extract regularly cause thyroid enlargement tachycardia elevation of the basal metabolic rate and creatinuria in normal human subjects In most cases of hypothyroidism the injections restored the metabolism to normal, but in some cases of hypothyroidism even massive doses failed to evoke a response, and biopsy of the thyroid isthmus in one such case showed appearances within normal limits We may conclude that the responsiveness of the thyroid epithelium is variable Hence it is possible that a pathological lack of responsiveness may account for the occurrence of exophthalmic ophthalmoplegia without goitre or raised metabolic rate

The term exophthalmic ophthalmoplegia is a useful one since it indicates the usual association of considerable exophthalmos with the muscular palsy Brain (1938) claims that exophthalmic ophthalmoplegia is a syndrome clearly distinguishable from exophthalmic goitre But the evidence here presented suggests that even when exophthalmic ophthalmoplegia is present without thyrotoxicity the condition is best regarded as an extension of the thyrotoxic syndrome and not as sharply distinct from it It seems desirable to use the term simply to denote a particular combination of eye signs occurring alone in conjunction with active thyrotoxicosis or as a complication after thyroidectomy Incidentally since the behaviour of the ocular and thyroid components of thyrotoxicosis is more or less independent, the state of both must be specified if the diagnosis is to be clear and adequate

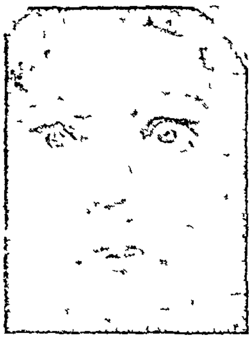

FIG 1—Postoperative exophthalmic ophthalmoplegia Both external recti are affected

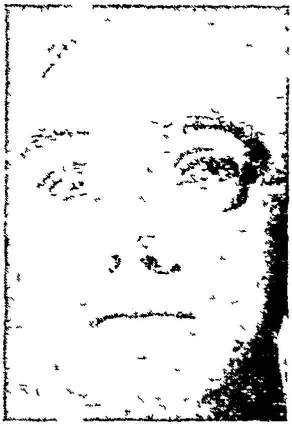

FIG 2—Exophthalmic ophthalmoplegia associated with severe thyroid intoxication Note chemosis and limited abduction of the left eye (photograph taken soon after thyroidectomy)

It will be seen also that exophthalmic ophthalmoplegia was associated with a normal or subnormal metabolic rate in two-thirds of the cases, and there is a suggestive comparison between this clinical group and certain experimental data Smelser (1937) found that gross proptosis followed the injection of anterior pituitary extracts in thyroidectomised but not in intact guineapigs He claimed that an increased bulk of the retrobulbar contents of the orbit caused the proptosis and was due to œdema of the tissues But the difficulty of arguing from results in the experimental animal to disease states in man is shown by the fact that the only case of exophthalmic ophthalmoplegia in the present series which came to autopsy, showed no œdema of the orbital fat when examined histologically

ANTECEDENT GOITRE

The importance of the thyroid factor in pathogenesis is suggested by the frequent development of thyrotoxicosis in patients already suffering from simple goitre It is suggestive that this secondary toxic goitre is fairly common even among city-dwellers Thus after excluding a small group of patients from an endemic area, 62 cases, or about 1 in 5 of the present series, gave a history of antecedent goitre Usually the previous goitre had appeared at puberty or during adolescence Sometimes it had subsided in adult life but the subsequent development of thyrotoxicosis indicated that the gland remained a locus minoris resistentiæ

There is also powerful evidence from goitre maps endemic goitre predisposes to thyrotoxicosis M don (1936) in the United States, McEwan (1938) in countiy and Wyndham (1940) in New South Wales made geographical surveys of the incidence of simple toxic goitre Each author found that the areas of est incidence of thyrotoxicosis coincided with the highest endemicity And, as is well known, exopht mos is not common in secondary toxic goitre, th intoxication being usually the sole manifestation observation may mean that the presence of simple predisposes more particularly to this component of thyrotoxic syndrome

In this connexion, an interesting experiment w described by Anderson and Collip (1934) A group rats suffering from spontaneous goitre was injected w the same dose of thyrotropic pituitary extract as a gro of control rats The goitrous rats w much more susceptible, and responded developing a hyperacute form of experimental thyrotoxicosis In one, the basal metabolism reached 262% of normal compared with an average of 120–130% for the controls Such a result is highly suggestive, but it should be noted that Remington (1937), working with rats in which goitre had been induced experimentally, was unable to obt confirmatory results In his experime the goitrous rats showed no increased susceptibility

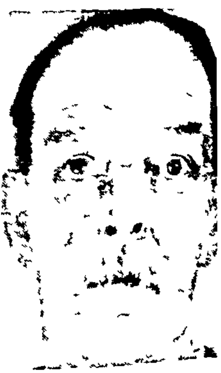

FIG 3—Exophthalmic thalmoplegia of the eye without goitre or hy metabolism Note siderable lid retraction

HEREDITY

The evidence that goitre arises as an heredit characteristic in certain families is strong In this se of 332 patients, 72 (22%) gave a family history of thy disease Different forms of thyroid disease occur simple goitre predominating (see table) Hence it is thyrotoxicosis specifically but rather the defec thyroid stock that is inherited

The main facts concerning the hereditary aspect thyrotoxicosis can be shown by representative cases

Family A—This family tree shows the goitrous diath in 3 successive generations (fig 4) Thyroid weakness sh itself irregularly as simple or toxic goi Here it is transmitted through fema but transmission through males does oc Moreover, demonstrated this family, go is neither tra mitted as simple Mende dominant no a simple re sive, if it w Mendelian d inant, all the dren in second and t generations would be affected Moreover, it cannot Mendelian recessive since goitre is present in both the mo and her children, even though the latter are heterozygous is suggested that some other unit character which predisp to goitre is transmitted with the genes and in suitable circ stances goitre or thyrotoxicosis develops

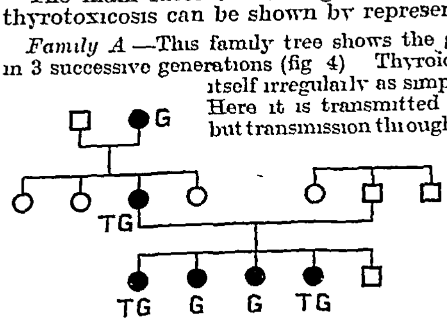

FIG 4—Family A Squares represent males circles females, those with thyroid disease shown in black G = goitre, T G = toxic goitre, H = hypothyroidism, M = myxœdema

Family B—This tree shows a particularly heavy incid of different types of thyroid disease in the same family (fig There were 2 members with toxic goitre, a third with m ying about Delusions of guilt (he thought he was in e way responsible for the German invasion of Holland) e prominent His orientation and memory for recent nts were faulty and he presented a picture of mild toxic fusion After a week in hospital he developed a septic otitis with pyrexia, and he collapsed and died suddenly days later Autopsy revealed necrosis and abscess formation in the parotid, patchy pneumonic consolidation and ngestion of both lungs, active congestion of the spleen with merous polymorphonuclear leucocytes in the pulp, hyper nia of the adrenals, central congestion with some hemo- erin deposits in the liver and no characteristic changes in e central nervous system In short, he had died from an ute septic process His brother in law stated that he was tremely unstable and over anxious and many times had ppeared to be on the verge of a nervous breakdown, but had ver actually had to enter hospital

THE EFFECT OF AIR-RAIDS

Later we had an opportunity of observing the effect f heavy and continued aerial attack in the cases admitted etween September, 1940, and February, 1941 Total dmissions amounted to 435 compared with 352 admitted between September, 1938 and February, 1939, and 57 between September 1939, and February, 1940 It ould be misleading, however, to draw conclusions bout the incidence of acute mental disorder from these igures, because the admission-rate was affected by variety of administrative factors The diagnoses ere: senile dementia, 150, other organic disorders, 2 depression, 82, mania 21, schizophrenia, 85, sychopathic personality, 10, psychoneurosis, 5 The ndromes encountered did not differ materially from hose met with in peace-time by Pentreath and Dax 1937), except that there was an increase in the proporion of senile cases The stress of the war situation was onsiderable in our cases, and was occasionally the chief actor, an experience of bombing precipitating the mental llness In other cases, however, bombing merely etermined the onset of a breakdown to which constituional and environmental factors had conduced

ACUTE TRAUMA

In a group of 13 cases 6 male and 7 female, the illness ad been preceded by exposure to a frightening or grief-roducing situation as a result of air-raids, and this as the chief precipitating factor The symptoms roduced were depression and anxiety, although in one atient a diagnosis of schizophrenia was considered ertain and in another probable At one end of the cale symptoms shaded off into normal emotional eactions The diagnoses were depression, 9, schizohrenia, 2, anxiety state, 1, state of panic, 1

Case 3—A woman, aged 31, was awakened by a bomb xplosion which shook the house For the rest of that night nd the next morning she trembled and shivered violently nd in the afternoon was seen running up a hill with her three-ear old son in her arms in a panic When asked what was he matter she said that the sirens had gone, which was untrue uring the night she became worse and talked incoherently, elieving that Hitler had turned the house into a dope den nd was doping her On admission to hospital next day she as in a state of acute anxiety, sweating, tremulous, with ilated pupils, exophthalmos and mild hyperthyroid signs er speech was mostly unintelligible For the succeeding 0 days she ran a high intermittent temperature and appeared larmingly ill at times, although no evidence of infection was ver found She was kept in the observation ward for a urther three weeks, during which time she had an uneventful onvalescence from a physical point of view, but comlained much of depression and of anxiety symptoms She ent home with her husband but experienced a return of ncontrollable panic and had to be readmitted within a few ours She was then transferred to a mental hospital as a oluntary patient where she made good progress and was scharged recovered after 3 months She was described by er husband as a jolly, sociable, industrious person, but had d one previous attack of anxiety and depression after the irth of a stillborn child Her mother had been treated for enopausal depression in a mental hospital

Case 4—A woman, aged 47, had her windows blown out d broken glass and other debris strewn over the bed in hich she was sleeping During the following night she ecame agi [illegible] auditorily hallucinated, believing that her dead husband was knocking on the roof On admission she was depressed, complained of severe headache, and expressed a delusion that her husband was still alive and in need of help She was at the menopause She improved rapidly and was discharged at the end of a fortnight in a slightly elated mood Her previous personality showed violent mood swings and she had made a suicidal attempt on one occasion, although mental hospital treatment had never proved necessary

Case 5—A woman aged 63, was sheltering under the stairs of her house when a bomb fell in the next garden, blowing out the windows and bringing down the ceilings, she became very frightened and depressed On admission she was depressed and somewhat retarded, complained of many anxiety symptoms and was full of gloomy forebodings as to the future course of the war It appeared that she had listened to Lord Haw Haw's broadcasts on several occasions and had incorporated his propaganda neatly into her psychosis dwelling on the folly of our politicians in involving us in war, on the overwhelming might of Germany and on our inevitable defeat She was transferred to a mental hospital as a voluntary patient There she became worse and died 3 weeks later from the exhaustion of melancholia

Case 6—A widowed charwoman, aged 50, was in a trench shelter when it was hit by a bomb, the woman next to her being killed Immediately afterwards she became depressed, would sit crying for hours, and was unable to go back to her work A few days later she attempted suicide by throwing herself in front of a train, and was admitted to hospital She was a typical agitated melancholic except for a paranoid formation which she developed against her brother with whom she had always been on good terms She insisted that he was responsible for keeping her son in the Army and that he came to the hospital to slander her and to poison our minds against her Her prepsychotic personality was stolid and unimaginative, with no outstanding traits Her previous mental and physical health had been good She made no improvement in the observation ward, refused treatment as a voluntary patient and finally had to be certified The mental hospital reports, 5 months later, that she is still extremely depressed and shows no sign of improvement

Case 7—A stretcher bearer, aged 52, was working on a damaged hospital when a bomb fell about 50 yards away Nothing was seen of him at his post for five days, but on the sixth day he returned in a state of agitation and depression, bitterly self-reproachful and declaring that his workmates all despised him Within the next day or two he became worse and had to be sent into hospital, where he was depressed, hypochondriacal and hopeless He was transferred to a psychiatric clinic, from whence he was discharged improved after a fortnight and returned to his work There was a history of shellshock in the last war and he seemed to have been a rather oversensitive, anxious, solitary person.

Case 8—A salesman, aged 23, had his wife killed and his home demolished by a high explosive bomb He was admitted, after an attempt to poison himself, in a depressed and actively suicidal state, but improved rapidly and was discharged recovered at the end of a fortnight

Case 9—A woman packer, aged 20, was with her family in an air raid shelter which received a direct hit Her father was killed and her mother and brother seriously injured She was admitted in a depressed and tearful state with little emotional control and exaggerated affective responses She made an excellent recovery and was discharged after a fortnight

Case 10—A labourer aged 65, who had always been healthy, was blown to the ground by a bomb explosion, sustaining slight concussion and a lacerated scalp Afterwards he became increasingly depressed and tearful and attempts to resume work ended in failure He was admitted to hospital two months after his injury and was then depressed with delusions of guilt and impending disaster He made little progress and was transferred to a mental hospital as a voluntary patient, after three months there he is reported to be showing little change

Case 11—A male clerk, aged 46, had had an illness labelled neurasthenia, in the last war but had served in the Army until 1919 without being invalided He returned from work one day last year to find his house demolished Fears were expressed that his wife was buried in the wreckage and it was not until several hours later that he learned that she was safe Immediately after this he became extremely depressed would sit for hours with his face in his hands and had to give up his work A fortnight later he was admitted to hospital therefore been cast on the importance of the anterior lobe In a recent paper Collard Mills, Rundle and Sharpey-Schafer (1940) have shown that too much credence has been placed on the negative results of previous assays They found that, while it is possible in man to produce experimental thyrotoxicosis by injecting thyrotropic extract, this cannot be recovered from the blood by the most sensitive of current methods Consequently inability to detect thyrotropic substance in clinical thyrotoxicosis would not necessarily mean that the anterior pituitary is unimportant in pathogenesis

Trikojus (1939) suggested that the negative results of blood assays in thyrotoxicosis are due to the fact that thyrotropic substance is fixed or in some way altered by the thyroid gland that it is stimulating But, when doses of extract sufficient to cause stimulation in normal subjects were given to patients with myxœdema who had no thyroid tissue to fix it, it was still impossible to recover evidence of its presence in the blood From their experimental data Collard and her colleagues (1940) deduce that no far-reaching conclusions can yet be drawn regarding the importance of the anterior pituitary in pathogenesis

THE NERVOUS COMPONENT

In considering the nervous component of the thyrotoxic syndrome we are on still more uncertain ground It is remarkable that in a certain proportion of cases palpitations, tachycardia nervousness, flushing and tremor outlast the stage of active thyrotoxicosis or persist almost unchanged after thyroidectomy It seems that the nervous pathways regulating the attacks of palpitations and tremor become so canalised during the active stage of the disease that these responses are facilitated afterwards and occur under even minor stresses Rasmussen (1937) claims that the symptoms of nervousness, tremor, palpitations, flushing and sweating under stress constitute a psychoneurosis which is a regular component of thyrotoxicosis, present during the acute stage but becoming relatively more prominent after thyroidectomy when the symptoms of hypermetabolism are relieved But it seems hardly justifiable to ascribe these symptoms to psychoneurosis Hyperexcitability of the nervous system is a well-known effect of the thyroid toxæmia, and when it persists after thyroidectomy it can as a rule be distinguished from a true psychoneurosis The distinction is of importance in prognosis and treatment for when a true psychoneurosis is associated with thyrotoxicosis there is usually a factor of psychic trauma or a psychopathic trait in the personality

Follow-up studies show that there is a comparatively heavy incidence of nervous disorder in patients after thyroidectomy, and this seems to favour the concept of thyrotoxicosis as a general neuro-endocrine disorder in which thyroidectomy removes only the most important of the glandular components, leaving untouched the fundamental disorder More particularly it has been claimed (Crile 1935) that persistent hyperexcitability signifies that a constitutional sympatheticotonia forms the background on which thyroid hyperplasia tends to develop But though it is possible that a labile autonomic nervous system predisposes to thyrotoxicosis, it is more than doubtful whether one or other division of that system is especially affected

SUMMARY

The eye changes of Graves's disease may develop apart from goitre or hypermetabolism Such cases favour an extrathyroid theory of origin

Exophthalmic ophthalmoplegia is found before or after thyroidectomy and occasionally in patients without goitre or hypermetabolism It is not a syndrome clearly distinguishable from thyrotoxicosis Cases in which goitre and hypermetabolism are lacking may be abortive forms of Graves's disease

There was a family history of thyroid disease in 22% of 322 patients with thyrotoxicosis Antecedent simple goitre had been present in 18%, 42% associated psychic trauma with the onset of symptoms, and in 20% the disease developed within 2 years of the menopause

Where there is a psychopathic personality or where psychic trauma is associated with the onset, psychoneurosis may coexist with thyrotoxicosis, but it is not an integral part of the syndrome

I wish to thank the staff of the Westminster Ho London County Council thyroid clinic for investigate cases in their charge and to publish these tions The work was aided by a grant from the John Cahill Research Fund

PSYCHIATRIC REACTIONS OF CIVILIANS IN WAR-TIME

ARTHUR HARRIS, M D Manc, D P M
MEDICAL OFFICER TO ST FRANCIS HOSPITAL OBSERVATION UN
L C C

EXPERIENCE in this observation unit sheds some ligh on the reactions, from a psychiatric point of view, of civilian population exposed to total war The patient admitted represent all urgent cases of mental disorde within a district whose population is 700,000, althoug patients from other parts of the London County Counc area are admitted at times Those who do not recov sufficiently to be discharged within a fortnight transferred to other hospitals The working of the u has been described by Pentreath and Dax (1937) a Butler (1940)

REFUGEES FROM INVADED COUNTRIES

The hospital is situated near a large refugee recepti centre and any cases of acute mental disorder there a transferred to the hospital Of the large number refugees who reached London at the time of the inva of Holland and Belgium many had been exposed terrifying experiences of actual warfare and hurr flight, 5 of these were admitted to hospital, but in the disturbance was trivial and cleared up after a night rest, and 1 was a chronic schizophrenic who had had t courses of insulin-shock therapy in Brussels In t remaining 2 a psychosis had been precipitated, as th case-histories show

CASE 1 —A single woman, aged 39, a clerk in the employ a Belgian municipal council, had to spend several days in t cellar with her family during a heavy bombardment Dur this time she appeared dazed and paralysed with frigh later, when the whole family were on a boat to England began to express delusions that they were surrounded spies, and pleaded with her family to take her home Wh admitted to hospital she misinterpreted events in a parano way, believing that a gang of spies were plotting to secu her passport for the use of one of their number, who was h double She was resentful and hostile and finally had to certified The mental hospital to which she was sent rep that she was there for 3½ months until she was killed in air raid During this time the clinical picture became creasingly dominated by depressive features and she to express delusions of guilt and impending According to her brother, she had been a shy solitary who had had few friends or interests and avoided the oppo sex She had a hasty temper and was liable to outbursts from which she soon recovered

CASE 2 —A commercial traveller aged 57, a British subj had had to leave his home in Holland in great haste Af suicidal attempt he was admitted to hospital in a state profound agitation, suffering from visual and haptic halluc tions and continually trying to blow off from his person "stupefying stuff" which he believed the Germans to

R P post when it was hit by a high explosive bomb incidents were separated by an interval of three days eceived no physical injuries but appeared shaken and had been neglecting his personal appearance and laughing crying for no particular reason His memory was aired, his mood was one of rather inappropriate euphoria he seemed to have little appreciation of his disabilities osition His pupils reacted sluggishly and were not quite ilar, and examination of his cerebrospinal fluid revealed t he was suffering from G P I

ASE 21 —A van driver, aged 50, was in bed when his house s hit by a bomb Afterwards he appeared muddled and ifused, his memory became bad, he tended to fabricate l his family had to wash and dress him His mental state admission was one of gross confusion and disorientation d there were signs of organic disease of his brain Six ys later he became comatose and two days after that he ed At autopsy a large cystic mass was found in his left mporal lobe which proved to be a rapidly growing highly alignant glioma

BORDERLINE INSTITUTIONAL CASES

Patients who have been precariously avoiding mental ospital treatment, thanks to the care of their relatives t home, have presented problems under air-raid conditions which had often necessitated their admission to he observation ward Senile dements were by far the ommonest type encountered under this heading, but ongenital defectives and chronic schizophrenics and psychopaths, whom their families had hitherto been able to look after satisfactorily, were also seen Old people living by themselves were unable to cope with the black-out regulations and other increased difficulties of their environment and became confused and frequently ostile and aggressive Old people living with their latives would refuse to go to shelters with the rest of e family and caused them much worry by insisting n staying in the house alone In this way they incurred e attention of the relieving officer sooner than would therwise have been the case

Case 22 —A woman, aged 81, had to be removed on account f bomb damage from the hostel where she had been living r some years to another belonging to the same organisation he failed to settle down in her new surroundings and became rogressively more restless and confused, her removal to ospital finally becoming necessary

Case 23 —The family of a mentally defective man, aged 4, had to leave their home on account of bomb damage He efused to stay at their new home in another district and eturned to the damaged house, but had to be removed from here by the police because he became acutely excited one vening, shouted, screamed and threw the furniture out of he window

Case 24 —A chronic schizophrenic, aged 35, who had been charged from a mental hospital into the care of his mother hree years before, became acutely excited because he was stled in an air raid shelter and had a violent outburst in hich he injured a small child

Cases of this type should be borne in mind in the terpretation of any increase in the mental-hospital opulation which may occur in war time, although our xperience does not suggest that the numbers involved re likely to be large

MISCELLANEOUS WAR-TIME STRESSES

The possible adverse war influences on civilians are t exhausted by the direct or indirect effect of air-raids other military operations

Case 25 —A German Jewish refugee who had been a man wealth and position before the Nazi persecution found himf penniless, refused permission to work and dependent charity His reaction to these unfavourable circumnces, from which he could see no escape, was one of increasg depression and hypochondriasis

Case 26 —A young man of psychopathic personality and mily history broke down with symptoms of a neurasthenic aracter when he had to attend his Army medical examinan. After this he gave up his work and when he received calling up notice made an ineffectual, hysterical suicidal tempt by scratching his wrist with a knife

GENERAL CONSIDERATIONS

The absence of cases of conversion hysteria or other sterical conditions is remarkable, and so is the rarity of organic confusion only one case of which was seen No instances of confusional states following exposure to blast, such as those described by Hemphill (1941), or of carbon-monoxide poisoning, such as might be anticipated in people trapped in damaged buildings, were seen

Causes in psychiatric disorders are always multiple With the help of a detailed and adequate history such as that obtained by a skilled psychiatric social worker from relatives and other informants, it is often possible to decide whether the preponderant cause of the illness is recent trauma, intrinsic conflict or psychopathic predisposition The question is of prognostic and therapeutic importance, and it has a considerable bearing on treatment and the measures to be taken

It has been said that since no general increase in psychosis occurs in war-time the stresses of warfare cannot be ætiologically important in that group of diseases (Bonhœffer 1919 Hemphill 1941) This argument is fallacious because it assumes that all other stresses remain constant whereas in fact many peacetime ones are considerably mitigated Difficulties connected with the finding of employment are a striking example and some unstable personalities seem to be well adapted to life in the Services, but tend to break down when confronted with the problems of civilian life Several authors have observed an improvement in war-time in chronic depressives and hypochondriacs which they ascribe to the increased opportunities for work and companionship (Mira 1939 Hemphill 1941) It seems more correct to suppose that in many cases war conditions are an added burden which may overwhelm those predisposed to mental illness, but that it is seldom possible to appraise the true part played by them without detailed study of the patient and his history

SUMMARY

Experiences in an observation ward near a refugee-reception centre and in a heavily bombed district are reported

War conditions may appear to have some ætiological significance in a wide variety of reactions, although depression and anxiety are the commonest disturbances produced by frightening and distressing events

Air-raids, during a period when they were heavy, appear to have been among the chief causes of breakdown in only 23 out of a total of 435 admissions Of these, 13 followed acute psychic trauma, 9 more prolonged stress and 1 cerebral contusion

There is a tendency for the socially unfit to gravitate towards institutions in war-time

I am indebted to Dr Allen Daley, chief medical officer of the L C C, and to Dr O W Roberts, medical superintendent of St Francis Hospital, for permission to publish this paper, to Dr Aubrey Lewis, psychiatric consultant to St Francis Observation Unit, for his opinion of the cases and help in the preparation of the paper, to Dr Alfred Meyer for histological investigations, and to Mr George S Burden for the social work involved

Rotenone Lotion (B D H) —Derris, familiar to the gardener and farmer as an insecticide contains 2–10% of its active principle rotenone, $C_{23}H_{22}O_6$, a crystalline substance insoluble in water but soluble in organic solvents Last year C C Thomas and E E Miller (*Amer J med Sci* 1940, 199, 670) reported rapid cure of 29 cases of scabies with a lotion containing 1–2% rotenone, and Leslie Saunders (*Brit med J* 1941, 1, 624) has since found a suspension of derris-root powder in soapy water as effective and cheaper, but perhaps more irritating Rotenone Lotion (B D H.) is a non-oily mucilaginous preparation containing 2% of rotenone. In mild cases of scabies application morning and evening for two days is said to be effective The lotion is free from smell and does not stain clothing and then complained of many symptoms of an anxiety type, appearing very miserable and stating that there was no hope for him and that he wished to die He improved very little and was transferred to a mental hospital as a voluntary patient Six months later his mental condition is not regarded as satisfactory, although he has been transferred to a general hospital for surgical treatment

CASE 12—A male shop assistant, aged 30, was badly shaken by a bomb explosion and his helmet dented while on his way to work He was a cheerful, sociable, even tempered person and a non smoker, but after this incident he became moody and difficult and began to smoke heavily A week or two later he began to suffer from auditory hallucinations and expressed a delusion that the Government were going to give him a high salaried job On admission, six weeks after the bomb explosion, he was auditorily hallucinated and said that he and his wife were under the control of a certain doctor who could force them to do things against their will He was transferred to a psychiatric clinic, where he made little progress and was considered to be schizophrenic on discharge

CASE 13—A waitress, aged 25, was sheltering in a crypt when a bomb explosion burnt her hand and killed her mother who was sitting next to her Next day she became very depressed and agitated, declaring that her inside was ruined, that she was going blind and that her death was imminent, and her removal to hospital was necessary On admission she presented a straightforward picture of agitated depression with delusions of disease and impending disaster, but later developed impulsive behaviour in response to hallucinatory commands and her hypochondriacal delusions assumed a bizarre, fantastic form She was transferred to a mental hospital as a voluntary patient They report 5 months later that her acute symptoms have subsided, but that she is dull, apathetic and dependent and needs nursing supervision She was of low intelligence and had always done rough and poorly paid work Her marriage was a failure and she had had to return to her parents, on whom she had always been very dependent

CASE 14—A clerk, aged 46, was buried with his wife and small daughter in their shelter when their house was wrecked by a bomb A fortnight later they were spending the night in a shelter when a bomb explosion put out the lights and burst some pipes with resultant flooding After this he became anxious and jumpy He was discharged after one day in hospital as he was unwilling to stay, and arrangements were made for him to go to the country with his family for a rest He writes 6 months later that he is still receiving psychiatric outpatient treatment and feels quite unfit for work

CASE 15—A woman, aged 89, living in an almshouse, had to move hurriedly to a rest centre on account of a delayed action bomb The same evening she became acutely agitated and hallucinated, declaring that Germans were pouring in through the windows and that they were all going to be killed She was removed to hospital and by next morning had regained her normal mental state with a high degree of insight into her illness, no further symptoms appearing subsequently She was discharged back to the almshouse when the time bomb had been removed

Cases 8, 9 and 14 approach normal emotional reaction, although an interval of about a fortnight separated the causal event and their admission to hospital The favourable outcome in the first two, in spite of the severe symptoms is noteworthy, and there seems to be a tendency for the outlook to be better when the trauma has been greatest, in other words, the more stable personalities can only be injured by blows of extreme violence, and possess good powers of recuperation A strong constitutional element is evident in cases 3, 4 and 11, they have shown a lifelong tendency to react in the same pathological way to a variety of adverse circumstances In case 10, age and possibly the aftereffects of concussion must be considered as factors Case 15 illustrates the effect of upset and disturbance on an aged person of fixed habits and routine The rapidity and completeness of the recovery is striking There was also a man of 63 who became confused and demented after a severe head injury sustained when his flat was bombed but he is obviously in a different category from these 13 cases, whose illness was psychogenic

PROLONGED AIR-RAID STRESSES

In some cases no single calamity had precipitated the illness, but a series of exhausting and alarming experiences acting for weeks or months Constitutional factors were also present, of course There cases in this category, but the war appeared to minor rôle in many more The diagnoses were sion, 5, schizophrenia, 2, mania, 1, exhaustion confusion 1 It became almost a polite con the relatives to attribute the illness to war stress, any bald statement of the kind should be sceptically

CASE 16—A man, aged 48, was admitted in a state fusion, exhaustion and mild delirium When the a started, he had refused to live at home with his wife family because the house had no shelter, he spent evenings and nights in tube stations, getting rather meals at cheap restaurants He had a one man which he had built up into a prosperous one by dint siderable exertions, but it had been adversely affected war and there was a possibility that he would have to down His personality showed strong obsessional and a pathological degree of anxiety, with a tendency to violent and excessive emotional outbursts over comparatively unimportant matters, and he had several times appeared to be on the verge of a breakdown He improved rapidly and was discharged recovered in a fortnight

CASE 17—An auxiliary fireman, aged 34, was admitted with a history of having become increasingly moody and sullen for a fortnight until his behaviour was obviously psychotic At the onset he had been subject to increased strain and considerable danger, since he had been out night after night fighting large fires in the middle of air raid He was auditorily hallucinated and expressed delusions that he had been kidnapped by a gang of white slave traffickers who were using him as a decoy in an effort to get hold of his mother and sister He did not improve and finally had to be certified The mental hospital to which he was sent report that he made rapid progress and was discharged recovered in just under 2 months, although shortly after his admission depressive features became prominent His parents emphasised the normality and goodness of his previous personality

CASE 18—A man, aged 55, a gas collector, was admitted a depressed, agitated and tremulous state He had been attending a psychiatric outpatient department for the year but had been carrying on with his work quite well For a few days before his admission the raids had been particularly heavy, he became frightened and finally broke down completely He improved considerably in hospital but was still far from well and was finally transferred to a mental hospital as a voluntary patient They report, five later, that he is still given to bouts of depression and hypochondriasis and is unfit for discharge

CASE 19—A man, aged 61, also a gas collector, was subject to considerably increased strain on account of air raids, he was caught in several daylight raids and had, in the course of his work, to clamber about the wreckage of bombed houses to search for the gas meter He was admitted becau wandered about restlessly, talking incoherently, and furiously with his wife and daughter with whom he previously been on the best of terms He was elated, rulous and over active, producing a constant stream incoherent talk, showing marked flight of ideas and heartily at the merest suspicion of a joke He voluntary patient treatment and had to be certified months later he is still at the mental hospital but has considerably and been given the status of a voluntary patient, his early discharge being anticipated

Cases 1, 12 and 17 constitute an interesting consisting of paranoid reactions arising as a result acute stress, cases 12 and 17 were normally people good personality and case 1 had not previously abnormal though she had always been solitary (1941) has described similar cases in serving The usual prognosis for schizophrenic states seem hold good, the later development of depressive fea reported from the mental hospitals is noteworthy Such cases illustrate the impossibility of saying exposure to any single experience, however shatt is the sole cause of a breakdown

MISLEADING CASES

The difficulties of making a prompt diagnosis and possible pitfalls are illustrated by the following cases

CASE 20—A stretcher bearer, aged 29, showed consid personality deterioration after two of

BLE II—PREOPERATIVE AND POSTOPERATIVE FINDINGS IN 7 CASES OF TETANY, COMPARED WITH FINDINGS IN CASES OF THYROTOXICOSIS AFTER SUBTOTAL THYROIDECTOMY UNCOMPLICATED BY TETANY THE CALCIUM AND PHOSPHORUS FIGURES ARE IN MG PER KG BODY-WEIGHT PER 3-DAY PERIOD

per 100 c cm in parathyroid tetany, when the urinary loss has had little time to be a factor

Phosphorus metabolism—Phosphorus excretion is diminished in parathyroid tetany after subtotal thyroidectomy for thyrotoxicosis and this is clearly demonstrated by studying the phosphorus balance Of the 7 patients, 3 had a positive phosphorus balance on an average intake of almost 0 39 g phosphorus daily The phosphorus loss is, however, also diminished in cases of thyrotoxicosis after uncomplicated subtotal thyroidectomy A comparison of the phosphorus balances in cases of subtotal thyroidectomy with and without tetany shows no significant difference, so it follows that the diminished phosphorus output detected in parathyroid tetany may partly or wholly be explained by the thyroidectomy

Sherman, Gillett and Pope (1918), and Sherman, Wheeler and Yates (1918) found that in normal subjects an average of 30% of the excreted phosphorus appeared in the fæces

TABLE III—CALCIUM AND PHOSPHORUS BALANCES IN A SEVERE CASE OF TETANY (CASE EV) FIGURES ARE FOR A THREE DAY PERIOD

—	Calcium				Phosphorus			
	Output (g)			Intake (g)	Output (g)			Intake (g)

Period 2	0 13	0 43	0 56	0 27	0 83	1 14	1 97	1 7
Mean	0 13	0 43	0 56	0 26	0 76	0 96	1 72	1 7

In the case of parathyroid tetany where the differential phosphorus excretion was measured (table III) it will be seen that as much as 56% of the phosphorus appeared in the stool This diminution of the urinary phosphorus excretion was also present in Aub's case In a study of phosphorus metabolism after subtotal thyroidectomy, Aub and others (1929) have reported on 6 cases of thyrotoxicosis In only 1 case did the percentage fæcal excretion of phosphorus fail to rise after operation The mean preoperative fæcal excretion of phosphorus was 27% of the total output, and after subtotal thyroidectomy this rose to 50% The low partition of phosphorus in the urine as compared with the fæces, which has been considered a feature of parathyroid tetany, is also found after subtotal thyroidectomy

In parathyroid tetany and after subtotal thyroidectomy there is a disturbance of phosphorus metabolism associated with a diminution in the phosphorus excretion in the urine In the above two groups thyrotoxicosis was present before operation and in both thyroidectomy was carried out It appears therefore that the diminished urinary excretion of phosphorus depends on one or other or both of these two factors and not on the parathyroid glands Albright and Ellsworth (1929) found a normal urinary excretion of phosphorus in idiopathic hypoparathyroidism

Serum calcium and inorganic phosphorus—Greenwald (1913) noted a rise in the phosphorus content of the blood after parathyroidectomy The relation of the serum calcium to the serum phosphorus at different levels of parathyroid activity has been studied by Albright and his colleagues (1931), who described a variation in the serum calcium and inorganic phosphorus ratio such that their product remained roughly constant They pointed out that this implied a considerable increase of phosphorus at low levels of calcium, and this is borne out by the observations in table IV

SUMMARY

The calcium and phosphorus metabolisms have been studied in 7 cases where tetany developed soon after subtotal thyroidectomy for the relief of thyrotoxicosis.

There is a diminished calcium excretion in tetany, and this seems to occur equally in the urine and fæces

It has been stated that a serum calcium of 8 5 mg per 100 c cm is the threshold value for urinary calcium excretion, and that below this level the calcinuria is negligible This is not supported, for observations on a patient with a serum calcium of 5 5 mg per 100 c cm showed that 23% of the calcium excreted was in the urine, which is a normal proportion

The urinary excretion of phosphorus falls in cases of tetany, following subtotal thyroidectomy, and is diminished to the same extent after uncomplicated subtotal thyroidectomy It seems that thyrotoxicosis followed by subtotal thyroidectomy, or subtotal thyroidectomy alone, brings about this fall, and that it does not depend on the parathyroids

This work confirms that a considerable increase in the serum inorganic phosphorus takes place at low levels of serum calcium

CALCIUM AND PHOSPHORUS STUDIES IN PARATHYROID TETANY*

J DOUGLAS ROBERTSON, M D D Sc St And D P H

THE syndrome of postoperative parathyroid insufficiency is characterised clinically by various types of paræsthesiæ, muscular pains and cramps, carpopedal spasm, laryngismus, and sometimes convulsions, all of which are aggravated by exercise There is a low serum calcium and high serum phosphorus The condition is due to resection or trauma of the parathyroid glands which brings about a cessation of their function in controlling the calcium metabolism of the body Postoperative hypoparathyroidism is not very common today because of improved surgical technique in thyroid surgery, but it may be unavoidable The metabolic characteristics of postoperative parathyroid tetany have been studied by Albright and others (1932) in a case that required two radical thyroidectomies for very mild Graves's disease

In the present paper 7 subjects have been investigated In all cases tetany developed a few days after subtotal thyroidectomy had been performed for the relief of thyrotoxicosis Except in one (case EV) no treatment was given for the tetany until after the metabolic studies had been completed In EV treatment for tetany was suspended during the actual periods when her calcium and phosphorus metabolisms were being studied

Results —Table I gives the results of the calcium and phosphorus balance in 7 cases of tetany, below, for comparison, are the corresponding findings in normal subjects and in cases of thyrotoxicosis successfully treated by subtotal thyroidectomy without complications It will be seen that the mean calcium output in tetany is lower than in normal subjects and in thyrotoxic patients after subtotal thyroidectomy In view of variations in the respective calcium intakes, the figure for the calcium loss (i e balance) is probably a more accurate index for comparison There is a diminished calcium loss in tetany compared with normal subjects and with treated thyrotoxicosis Calculated according to Fisher's P test (1938) the difference between the calcium loss in tetany and in normal people is significant ($P = 0 02$), as also is that between the loss in tetany and after thyroidectomy ($P < 0 02$)

Variations in the phosphorus intake by as much as 0 43 g per three-day period made it advisable to study the phosphorus metabolism by comparing the balances instead of the outputs It will be seen that the mean phosphorus loss in tetany is only 1 02 g per period, compared with the normal loss of 10 54 g and the loss after uncomplicated subtotal thyroidectomy of 2 41 g By Fisher's P test the difference between the phosphorus loss in tetany and normal people is significant ($P > 0 01$), but so is the difference between the phosphorus loss after uncomplicated thyroidectomy and in normal people ($P > 0 01$) It should follow therefore, that there is no significant difference in the phosphorus loss in tetany and in thyrotoxic patients after subtotal thyroidectomy without tetany, and such is the case ($P > 0 6$)

Table II gives the full preoperative and postoperative details of the calcium, phosphorus and basal metabolism in the 7 cases of tetany, with the corresponding figures in 30 cases of thyrotoxicosis uncomplicated by tetany after subtotal thyroidectomy Except for the difference in the calcium metabolism during tetany the findings in each group are alike, and it seems the occurrence of tetany does not depend on a particular type of patient but on a surgical technique The basal metabolism is normal in tetany

In table III are set out the calcium and phosphorus balances over three-day periods in a severe case of tetany where the output in the urine and fæces was determined separately It will be seen that there is a diminution in the excretion of calcium both in the urine and fæces compared with the normal figures of Bauer, Aub and Albright (1929)

In table IV are given the serum calcium and inorganic phosphorus in 10 cases of postoperative parathyroid tetany In case FF serial observations were made as she was progressing to recovery It will be seen that as the serum calcium fell so the serum inorganic phosphorus rose

DISCUSSION

Calcium metabolism —In a study of 7 cases of tetany there was found to be a diminished *calcium loss* which is in agreement with the case reported by Aub and his colleagues (1932) These authors found that the diminution in calcium excretion was in the urine and that the fæcal excretion of calcium was normal On these findings they postulated that the excretion of calcium in the urine was a threshold phenomenon while the fæcal excretion was not Albright, and Ellsworth (1929) had previously pointed out that a serum calcium of 8 5 mg per 100 c cm was the threshold for urinary calcium excretion Below a serum calcium of 8 5 mg per 100 c cm the calcium in the urine remained negligible The findings of Aub and his co-workers are not entirely supported by the case reported in table III With a serum calcium of only 5 5 mg per 100 c cm 23% of the total calcium excretion was passed in the urine, which agrees well with the 24% obtained by Bauer Aub and Albright (1929) for the calcium output of normal people If there is a threshold value for urinary calcium excretion in the region of 8 5 mg per 100 c cm, then it is an unusual phenomenon that the normal serum calcium level of 10 4 mg per 100 c cm should exceed it, and that the calcinuria does not soon lower the serum calcium to the threshold level Aub and his colleagues (1932) have sought to overcome this difficulty by postulating another mechanism which keeps the serum calcium above the threshold—the parathyroid hormone This, however, does not adequately explain the rapid fall in the serum calcium to well below 8 5 mg

SUMMARY

The calcium and phosphorus metabolisms have been studied in 7 cases where tetany developed soon after subtotal thyroidectomy for the relief of thyrotoxicosis

There is a diminished calcium excretion in tetany, and this seems to occur equally in the urine and fæces

It has been stated that a serum calcium of 8 5 mg per 100 c cm is the threshold value for urinary calcium excretion, and that below this level the calciuria is negligible This is not supported for observations on a patient with a serum calcium of 5 5 mg per 100 c cm showed that 23% of the calcium excreted was in the urine, which is a normal proportion

The urinary excretion of phosphorus falls in cases of tetany, following subtotal thyroidectomy and is diminished to the same extent after uncomplicated subtotal thyroidectomy It seems that thyrotoxicosis followed by subtotal thyroidectomy, or subtotal thyroidectomy alone, brings about this fall, and that it does not depend on the parathyroids

This work confirms that a considerable increase in the serum inorganic phosphorus takes place at low levels of serum calcium

A CASE OF RECOVERY FROM CRUSH SYNDROME

C J LONGLAND,
M B LOND , F R C S
JUNIOR SURGEON TO STOKE MANDEVILLE HOSPITAL

JOHN MURRAY,
M B CAMB
JUNIOR ASSISTANT PATHOLOGIST, E M S CENTRAL LABORATORY, SECTOR 5

IN the following case oliguria, hæmaturia, uræmia and jaundice followed burial under explosion debris and ended in recovery after treatment in which whole-blood transfusion played no part The treatment combined high fluid intake and alkalinisation on the lines suggested by Baker and Dodds for mismatched transfusion

A man of 51 was buried under bomb debris for four hours, making it impossible for him to move and indeed even difficult to breathe He was rescued in a dazed condition and at once taken to hospital On admission he was cold and shocked, B P 110/70, pulse rate 124 , he rapidly became comatose and his blood pressure fell in three hours to 60/35 He then received three pints of filtered plasma and three pints of filtered serum, having a severe rigor with one bottle As a result of transfusion, his B P rose in four hours to 88/65 and in a further six hours to 100/60 (see figure)

He was evacuated from London to this hospital in the afternoon of the next day, and his injuries were then found to be a fractured pelvis without visceral involvement and extensive bruising of the right side of his body and thigh On the second day he was mildly jaundiced, a little confused and retarded mentally, and passed a small amount of urine loaded with albumin and containing blood The blood urea was 197 mg per 100 c cm , B P 120/60 and the pulse rate 104 During the next five days the blood urea mounted steadily to 375 mg , though the urinary output had risen progressively from 8 to 32 oz per day and the B P had reached 180/105 His muscles, apart from the large subcutaneous bruises, showed no evidence of gross damage and there was no swelling or peripheral circulatory impairment The hæmoglobin was 50% His general condition altered very little , he suffered from abdominal distension at first and towards the end of the first week developed hiccoughs and slight muscular twitching He never vomited Treatment consisted of the administration of 2 pints of normal saline intravenously on the third day and 16 oz of 3 3% sodium sulphate on the fifth day to supplement a fluid intake by mouth of about 3 pints daily Potassium citrate was given from the third day, but the urine did not become alkaline till the sixth day with a dosage of gr 360 of potassium citrate daily On that day large numbers of pigment casts appeared in the urine , red cells only were occasionally seen subsequently As the blood urea continued to rise decapsulation was considered, but when on the eighth day the urea level showed a slight fall this proposal was abandoned The urea level continued to fall and was followed in a few days by an impro his clinical condition This was maintained, and four from the injury his blood-urea had returned to 42 mg , his to 156/100, and his urine contained less than 0 01% pro

DISCUSSION

It seems probable that the train of symptoms descri resulted from a sudden hæmolysis and that tissue destruction by crushing may liberate a hæmolysin and thus produce a hæmolytic jaundice and blockage of the kidney tubules Severe compression of tissue for a long period causes the accumulation of metabolites and especially of lactic acid, producing an acidosis This with a diminished urinary secretion due to the low blood pressure of secondary shock produces the optimal conditions for the deposition of acid hæmatin in the tubules of the kidney [1]

In the present case there is evidence of the loss from the circulating blood of at least a third of its hæmoglobin content Furthermore, in man during secondary shock according to Keith,[2] a blood-pressure of less than 70 mm Hg represents a loss of over 30% of the blood-volume We therefore calculate from the blood-pressure (60 mm Hg) and hæmoglobin readings (50% Haldane) on admission that at least 2000 c cm of whole blood were lost to the circulation without external bleeding The hæmoglobin loss represents more than 200 grammes Some bleeding occurred into the tissues, and it would only require a portion of the lost hæmoglobin to reach the kidneys to produce the observed syndrome , for it has been shown that the liberation of 87 g of hæmoglobin into the circulation from a pint of mismatched blood is certainly lethal, if conditions in the kidney are such that precipitation of acid hæmatin takes place—i e , a urine with a pH of 6 and a high salt content

We suggest that a major factor in the production of the crush syndrome in this case was hæmolysis in the presence of acidosis brought about by tissue injury and compression It may be argued that the pigment casts may have contained myoglobin,[3] but the clinical picture did not suggest much muscle damage, and there is no doubt that a large quantity of hæmoglobin was suddenly lost In addition in a sensitive patient the large trans fusion of serum and plasma might provide the hæmolysin, but this is rendered very unlikely by the known low level of agglutinins in the pooled blood derivatives in use The hæmoglobin estimations were controlled by complete blood-counts which showed no red-cell abnormality It would be interesting to see if such cases could be prevented by the intravenous injection of say 8 gramme

Findings in case reported Intravenous infusions (1) 3 pints filtered plasma and 3 pints filtered serum, (2) 2 pints normal saline (3) 16 oz of 3 3 % sodium sulphate

of sodium citrate before moving the injured from their cramped position

SUMMARY

A case is described in which uræmia following crushing and shock requiring large volumes of serum and plasma was successfully treated by alkalis and a high fluid intake

---

ISOLATION OF HÆMOLYTIC STREPTOCOCCI FROM WOUNDS

A E Francis M D Lond , M R C P
MAJOR R A M C

During the past six months approximately 2000 swabs from burns and superficial wounds have been examined bacteriologically with special reference to the presence of hæmolytic streptococci A number of methods have been found useful

Gentian violet blood-agar —It was shown by Garrod (1933) that all species of streptococci are more resistant to the bacteriostatic action of gentian violet than any staphylococci A medium containing the dye in a concentration of about 1 in 500,000 will yield a pure growth of streptococci from a mixture with staphylococci in any proportions Gentian violet blood-agar plates have been in routine use in his laboratory for some years for the cultivation of material containing numerous staphylococci, if the presence of streptococci is also suspected Garrod (1936) also pointed out that bacilli (aerobic spore-bearers) and yeasts are even more easily inhibited than staphylococci Diphtheroid bacilli which are often very numerous in superficial wounds, have also been found to be completely inhibited

The method I have used is to prepare a stock solution of 0 5% gentian violet in distilled water, and to make a 1 in 50 dilution of this in small quantities (since the 1 in 10,000 solution tends to precipitate after 4–6 weeks with some samples of the dye , 2 ml of this dilution are added to each 100 ml of melted agar, which is then prepared as blood agar and poured into plates in the usual way A single plate may be prepared by adding 0 3 ml to a 15 ml melted agar " stab The resulting plates do not differ in appearance from the usual blood-agar plates, and must be marked in some way

A series of 300 swabs have been inoculated in parallel on plain blood-agar and on gentian violet blood-agar plates Of a total of 102 (34%) positive by either method or by both, 68 (22 7%) were positive on plain blood-agar, but 98 (32 7%) were positive on gentian violet The growth of hæmolytic streptococci was often profuse on gentian violet, even when there were no colonies to be seen on blood-agar , 34 (11 3%) of the cultures were positive on gentian violet only , 4 (1 3%) were positive on plain blood-agar but negative on gentian violet None of these 4 supported the possibility that gentian violet had had any inhibitory action on the streptococci 1 faultily prepared plate was found to be completely hæmolysed, which made the recognition of hæmolytic streptococci difficult though they had, in fact grown ; in another the gentian violet was almost covered by colonies of *Pseudomonas pyocyanea* which like other gram-negative bacteria, is not inhibited , the 2 others gave only one colony and three colonies on blood-agar The use of gentian violet blood-agar plates therefore produced an increase of 50% (from 68 on plain blood-agar to a total of 102) in the number of cultures shown to contain hæmolytic streptococci

Anaerobic blood-agar plates —Incubation of blood-agar plates under anaerobic condition sometimes reveals the presence of hæmolytic streptococci when these are not seen on plates incubated aerobically (Fry 1933) Owing to the limited facilities available for anaerobic culture, no figures for comparison with gentian violet can be presented This requires further investigation

STREPTOCOCCI IN THE PRESENCE OF OTHER ORGANISMS

Proteus was present in many wounds and it was found that a very few colonies would suffice to produce a film covering the whole plate *Ps pyocyanea* was likewise troublesome, since a small number of the large colonies of this organism occupied a considerable part of the area of a plate To overcome this difficulty the following methods were used

1 *Modified method of Fry* (1932) —A blood-agar plate is inoculated in the usual way, and is then covered with a layer of melted agar which has been cooled to 46° C When this has set firmly the surface is flooded with absolute alcohol, and after one minute this is poured away The plate is then dried in the inverted position in the incubator for 15–20 minutes before the lid is replaced

A series of 60 swabs were examined by this method when previous cultures had yielded a growth of proteus or *Ps pyocyanea* , in 18, hæmolytic streptococci were recovered though the blood-agar plate had *apparently* been negative in the presence of proteus or *Ps pyocyanea* The streptococci may be subcultured for further examination by picking through the layer of agar with a straight wire This method has the disadvantage that only colonies of hæmolytic streptococci can be recognised by naked-eye inspection

2 *Phenol blood-agar* —Where it is desired to study the flora of a wound in the presence of proteus or many *Ps pyocyanea* the incorporation of phenol, 1 in 1000, has been found useful (Braun and Schäfer 1919) Phenol is somewhat inhibitory to all bacteria in the concentration used, so it is essential to inoculate a plain blood agar plate in addition to the phenol plate If proteus is absent, hæmolytic streptococci may sometimes be recovered from blood-agar when the phenol has inhibited their growth Agar is melted and cooled to 46° C , then 2 ml of aqueous solution of phenol (5%) is added to each 100 ml of agar, and thoroughly mixed before the blood is added The cooling and thorough mixing are essential points in the preparation of these plates, which will otherwise not give satisfactory results

A series of 120 swabs have been cultured on this medium , 11 yielded colonies of hæmolytic streptococci when the plain blood-agar plate was rendered useless by the presence of proteus or many colonies of *Ps pyocyanea* In 6 cases, however, hæmolytic streptococci were recovered from plain blood-agar when the phenol had inhibited their growth Both plates were positive in 10 cases Thus means that a total of 16 swabs shown to contain hæmolytic streptococci on plain blood-agar was raised to 27 by the addition of a phenol blood-agar plate In addition, other bacteria may be clearly recognised proteus grows in grey, translucent, hemispherical colonies with thin, radial projections, giving a spider-like colony, *Ps pyocyanea* produces tiny, colourless, transparent colonies, as do most other coliform bacilli A few strains of proteus have been encountered which produce a spreading growth on this, as on other media

3 *Sodium azide*—Snyder and Lichstein (1940) recommended that sodium azide should be incorporated in blood-agar plates for the isolation of hæmolytic streptococci in the presence of proteus In my experience it turns horse blood agar plates brown, and causes the blood to lake This makes colonies of hæmolytic streptococci difficult to recognise It has also failed to inhibit the spread of proteus when inoculated either with diluted cultures or with swabs from wounds containing this organism The use of sodium azide has therefore been discontinued

SUMMARY

Hæmolytic streptococci may be recovered, often in profuse culture, from blood-agar plates containing 1 in 500 000 gentian violet, when cultures on plain blood-agar are negative Of 300 swabs, 68 were positive on blood-agar, while 98 were positive on gentian violet

If proteus or many *Ps pyocyanea* are present in material for culture hæmolytic streptococci may be recovered by covering the inoculated plate with melted agar and sterilising the surface of this with absolute alcohol, or by inoculating a blood-agar plate containing phenol, 1 in 1000 Sodium azide has not been found useful

I am indebted to Sir Harold Gillies for access to cases under his care, to Colonel L Colebrook for criticisms and suggestions, and to Dr V Lindley Connolly, medical superintendent of Park Prewett Hospital, for permission to publish this paper

CEREBRAL HÆMORRHAGE
IN AN INFANT BORN BY CÆSAREAN SECTION

C Paget Lapage, M D Manc, F R C P
PÆDIATRIC PHYSICIAN TO THE MATERNITY DEPARTMENT OF SAINT MARY'S HOSPITALS MANCHESTER

The following case shows how an extensive cerebral hæmorrhage can occur without a prolonged labour The mother was under the care of my colleague, Dr Robert Newton Dr Katherine Leibert, acting resident obstetric surgeon, reported as follows

Primigravida, aged 36, in good health Urine normal B P 155/85 Shortly after the onset of labour a lower segment cæsarean section was performed for malpresentation The child was lying obliquely in the uterus, and did not alter its position with the onset of labour The presentation was a breech L S A The child weighed 8 lb 12 oz and was very asphyxiated at birth, she was given a hot bath, and CO_2 and oxygen and made a good recovery She made good progress until the third day, when the temperature rose to 103 8° F and the child became irritable On the fourth day the temperature was 99° F, and the hands were tightly clenched with the thumb adducted across the palm under flexed fingers The chest showed no abnormality Hypertonic salines and vitamin K were given On the fifth day the temperature rose again to 105° F and a right facial paralysis developed The limbs were spastic, the eyes staring On the seventh day some improvement took place, the child being less irritable and the limbs slightly less spastic, the temperature was 105 4° F On the ninth day she had a series of severe convulsions and was very cyanosed Oxygen was given Temperature 101° F. She died on the tenth day

Autopsy (Dr William Susman)—Myocardium on left side much thickened, ductus arteriosus completely patent Hypostatic congestion of lower lobes of both lungs Œsophagus shows intense passive congestion Stomach contains altered blood Cut surface of liver contains comparatively large areas in which normal liver structure is not prominent, throughout whole surface there are numerous small areas of congestion or hæmorrhage, probably hæmorrhage, microscopic examination showed a great deal of fatt including degeneration, also a pronounced degree of congestion Spleen intense passive congestion bilateral hæmorrhages involving chiefly medullary el Kidneys intense passive venous congestion through large collections of myelin in medullary pyramids, scopic examination shows a moderate degree of degeneration, considerable areas show severe atroph tubules and scattered tubules containing hæmatox reacting homogeneous material of a pseudocalcified app ance and with some foreign body reaction, section a whole shows much congestion with scattered hæmorrhag few arachnoid spaces at the base show profuse hæmorrh Brain almost whole of white matter of left hemispl replaced by blood clot with involvement of ventric lesion in right hemisphere similar but not extensive anterio and posteriorly, microscopic examination shows numer small hæmorrhages associated with generalised congestion well as thrombosis of some of the smaller vessels

Dr Susman's report shows the extensive nature of cerebral hæmorrhage He believes it was due to the pas congestion and tendency to thrombosis This asso tion of thrombosis and hæmorrhage was also evid in the adrenals, and was probably recent There no duodenal ulcer Such an extensive cerebral hæm rhage with no observable relation to mechanical force any kind indicates that factors other than mechanic such as deficiency of vitamin K, may be potent causing cerebral hæmorrhage in the newborn This been pointed out before, but is in need of further emphas

Reviews of Books

The Emperor's Itch

By Reuben Friedman, M D, assistant professor of derm tology and syphilology, Temple University School of Me cine, Philadelphia New York Froben Press Pp 82 $1

Scabies—Civil and Military

Same author and publishers Pp 288 $3

Dr Friedman knows his scabies, and in his ra written monograph seeks to prove that Napoleon ne suffered from this disease This is in direct contradict to the opinion of the majority of medical historians wh evidence he carefully sifts Dr Friedman suggests t the chronic skin disease from which Napoleon is kno to have suffered for the greater part of his life dermatitis herpetiformis His arguments are certai convincing The second of these books represents astonishing piece of research which will appeal stron to the lover of statistics Dr Friedman tells of scal among the early settlers in the New World and of treatment during the American Civil War He prov tables showing the loss of man-power due to scal in the American Army and the relative incidence of t infection among white and coloured troops, and discusses every known form of treatment Derm logists in this country will all agree with Dr Friedm basic statement that "an increase in the incidence scabies is the inevitable accompaniment and conseque of war"

A Complete Outline of Fractures

By J Grant Bonnin, M B Melb, F R C S, first assi to the injury clinic, West London Hospital Londo William Heinemann Pp 507 25*s*

Mr Bonnin's book is written primarily for the stude He gives a simple straightforward account of fractu and their treatment, and the illustrations are clear adequate There are separate chapters on appar t most of which is standardised and can be easily obtain and on that important subject, plaster technique, wh is well described The inclusion of fractures of the f and skull is unusual in such a book, for the former usually the concern of the plastic surgeon and the lat that of the neuro-surgeon but they are not really out place in a book to be used by those working in a casua department The section on compound fractures somewhat lacking in detail and the use of the sulphon amides is not sufficiently stressed, but apart from these minor deficiencies this is a well-written and produced book which will be helpful to all students and house officers and to many of their seniors as well

HALF MEASURES IN DIPHTHERIA

DIPHTHERIA has taken one of its turns Less loquially it is in course of one of its periodical ases of prevalence and enhanced severity More- er, in the months ahead it is likely to be a bigger ave than it would have been in peace-time conditions nless that is mass immunisation is speeded up onsider Birmingham a pioneer in preventive fore- ght and possibly still, despite misguided propa- andists one of our better immunised cities During he first six months of this year 600 genuine cases of iphtheria were reported and of these 56 were fatal an appalling fatality-rate of 9 3 per cent), compared with 336 cases and 16 deaths in the corresponding period of 1940 (a fatality-rate of 4 7 per cent , more normal but still appalling) Consider Scotland, where the tide seems to have set in earlier , during 1940, it has recently been stated 676 children died from the disease as compared with an average of 410 during the previous four years—an increase in fatalities of 65 per cent What then are our sanitary authorities doing about it ? Both the Ministry of Health and the Scottish Health Department have been lavish with advice and free prophylactic, and in some localities the public has responded well this spring and he campaign has made good progress The time may have come for standardising a model campaign A preliminary inquiry, not yet published, by the Committee for the Study of Social Medicine, seems to ndicate that direct personal propaganda brings in more onverts than posters, cinemas or wireless talks In Scotland where recent figures are available, nearly 30,000 out of a total child population of $1\frac{1}{8}$ millions being 47 per cent) have been immunised up to mid-July In Edinburgh over 65,000 children have been protected, most of them within the last six months in the corporation schools the inoculation-rate stands at 78 per cent But Edinburgh s medical officer is dissatisfied with these figures for his city , he aims to immunise 80 per cent of all the children And in all but a few districts outside Edinburgh the percentage of protected children remains dangerously low efforts having been concentrated mainly on school-children, whereas the age of greatest risk to life is from one to four years To immunise school-children and neglect those of pre-school age is a half measure—easier no doubt to put through, but misleading to the public If resources are limited it would be far more profitable to the community to concentrate upon the pre school child Nearly ten years ago GODFREY[1] showed that immunisation of half the school-children has no effect upon the incidence of diphtheria in a community unless a third of the children of pre-school age have also been immunised This achieved, an immediate and definite decline in current prevalence " ensues

Effective immunisation means at least two properly spaced doses of an efficient prophylactic The one-shot method is a shot in the dark , those who employ it are inviting a crop of lapsed immunes and the discrediting of the local scheme It is better to secure solid immunity for fifty children than semi-immunity for a hundred The Scottish department has advocated a simple scheme[2] based upon sound experience and advice It is as follows for children from nine months to eight years of age, two doses of A P T (0 2 and 0 5 c cm) at an interval of not less than four weeks , for children over eight, three doses of T A F (1 c cm) at intervals of not less than two weeks The Ministry of Health advocates[3] the same doses of A P T at the same intervals Unfortunately for the uniformity of practice which is so desirable in this work of national importance the Emergency Public Health Laboratory Service recently recommended that A P T issued free to local authorities should be injected in doses of 0 1 and 0 3 c cm This may have been a temporary measure to tide over a passing difficulty in supply, but it had the result of encouraging experiment in dosage not founded upon knowledge of the average state of basal immunity of the local population This local knowledge can only be gained by such extensive Schick testing as was practised years ago by W H PARK and A ZINGHER in America Properly carried out and accurately read the Schick test remains, what it has been these twenty-five years and more a trustworthy if not infallible indicator of susceptibility to diphtheria toxin We sympathise with BOUSFIELD[4] in his lack of patience ' with people who argue that the test is not worth while because occasionally Schick-negative children develop mild or moderate diphtheria " After long experience he ' is certain that the Schick-negative state is an almost water-tight insurance against death and, after all, that is what most people want to know ' The Schick test is not a back number It is in constant use in large fever hospitals not only to detect non-immunes and potential sensitives among the nursing staff but also, combined with swabbing and cultural (tellurite) tests, as an aid in the differentiation of the dubious case It is the only ready means of ascertaining whether in fact ' immunisation ' has produced a satisfactory level of immunity

The clinic worker who justifiably omits routine Schick tests in young children is unwise if he also omits to test at least samples of his handiwork after a reasonable interval , and none would be so reckless as to issue a certificate of immunity, as distinct from immunisation, unless he had satisfied himself that the Schick test was negative This testing of presumed immunes is all the more necessary because it seems there is A P T of high antigenic value and a p t (a poor thing) possessing little or none Most unfortunately some of the latter has formed part of the free issue to local authorities The prophylactics made in this country must conform with the Therapeutic Substances Regulations (1931) but it is probable that to meet a sudden demand, which depleted existing stocks, prophylactic of unaccustomed origin was issued as an emergency measure The incident should be capable of ready adjustment and is unlikely to recur It will have served a useful purpose if it establishes once and for all that immunisation against diphtheria, as a procedure of national importance, should be carried out upon national, not parochial, lines The Government should provide a standard antigen, lay down a standard dosage and insist upon children of pre-school age being given precedence The taxpayer who is providing the tools has a right to the assurance that they are being properly used And by the winter a preventable disease will have been prevented

DANGERS OF BREECH DELIVERY

ONE of the changes in obstetric practice in the last ten years or so has been the almost universal adoption of external cephalic version as a means of avoiding the difficulties and dangers of breech delivery On the wisdom of this there is little dispute, though the procedure itself is not devoid of risk But there are still differences of opinion about policy and technique when version is impossible and the fœtus must be delivered by the breech, as was lately demonstrated in our correspondence columns Some years ago **GIBBERD**'s[1] analysis of the results obtained in four London and four provincial teaching hospitals focused attention on the danger to the fœtus of breech delivery His views perhaps erred on the side of pessimism, but there is no doubt about his main contention—that the fœtal mortality of breech delivery, especially in primigravid women, was much higher than was generally supposed The figure of 25–30% reported by **GAIRDNER** and the **JACKSONS**,[2] from their analysis of hospital and private cases in which version failed and a full-sized infant was delivered vaginally, is by no means exceptional As **CHASSAR MOIR**[3] puts it, a patient about to have almost any standard major operation—for example, the removal of a pituitary tumour—faces a better chance of survival than does a full-sized fœtus of a primigravid woman which is about to be extracted breech first by a doctor of average experience But this picture is not always true, individual workers have been able to reduce the mortality of their breech deliveries to a very low level Thus **BURNS** and **MAYEUR**[4] can report a combined fœtal and neonatal death-rate at the Liverpool Maternity Hospital of only 6 2% (3 7% when strictly analysed) Still better results are reported by **E M HANSEN**[5] of Nebraska—omitting deaths due to prematurity, malformation and placenta prævia, a fœtal mortality of 0 8% in 126 private cases This figure would be good for normal delivery, and indeed **I W POTTER**[6] of Buffalo, famous for his method of conducting podalic version, and with experience of many thousands of breech extractions, claims that his fœtal mortality is little greater than that of normal birth These examples show that experience counts for more in breech delivery than in almost any other obstetric operation But while the rough ways can be made smooth, experience is dearly bought, and to the average practitioner breech delivery remains an anxious and uncertain event

Breech presentation is often the visible sign of other abnormality—contracted pelvis, malformed fœtus, placenta prævia and so on—and much of the of individual workers lies in skilful antenatal of underlying abnormalities Long experience taught **POTTER** to recognise the case in which delivery is safe and sure, and he makes no of the fact that a fair proportion of his patients delivered by abdominal section Paradoxically, proportion rises sharply in primigravid women whom the fœtus already presents by the breech **GAIRDNER** and his colleagues also advocate the freer use of cæsarean section, and in Liverpool the operation was performed in 8% of the cases That abdominal delivery is justifiable for the primigravida in the last few years of reproductive life, or for the woman of known low fertility, has long been agreed. but that the operation should be extended to include other types of case may seem a dangerous proposition Cæsarean section carries a small but stubborn mortality, yet if there is a considerable chance that a fœtal life will otherwise be lost is not this risk justifiable ? It must also be remembered that a difficult breech extraction often leaves the mother a damaged woman

The answer resolves itself into a skilful selection of cases Those women in whom a mechanical difficulty is likely to arise constitute less than *20% of the* whole, if it were possible to eliminate *these* "suspects" breech delivery would at once become far less anxious and formidable In vertex presentations the doctor is able by direct means to estimate the fit of the fœtal head in the pelvic brim, but in breech cases no such easy means is available to test the relative sizes of passenger and passage, progno can then be extremely difficult Here **MOIR**,[7] in his paper on the detection of pelvic contraction, lays stress on the help to be obtained from X-ray pelvimetry, especially from examination of the lateral view of the pelvis X-ray cephalometry can also be readily applied to the head which lies in the upper pole of the uterus **MOIR** urges that such examination should be a routine in every breech case, by their use the likelihood or otherwise of mechanical difficulty would be foreseen By this and other improved methods of antenatal examination much could be done to lessen the danger of breech delivery Cases likely to cause difficulty can be referred to special hospitals with facilities for operative treatment The "easy" remainder—and they constitute the bulk of cases—can then with far less anxiety be delivered in the patient's own home

NERVOUS COMPLICATIONS OF SULPHONAMIDE THERAPY

SINCE the introduction of the sulphonamides the nerve lesions which may complicate the acute infections seem to have been less rare, presumably because more patients with severe infections now survive long enough to develop them, but these have to be distinguished from the peripheral neuritis which may be produced by the drugs themselves Clinically the course of the two is different In the septic type the lesion is either a radiculitis, especially in streptococcal infections, or is confined to the ulnar or peroneal nerve, which becomes acutely painful and tender, with paresis of the muscles it supplies The phonamides, on the other hand, produce progres- e paræsthesiæ of the extremities with muscular akness beginning in the small muscles of the hands d feet and gradually spreading centrally, accom- nied by sensory and reflex loss; in one or two treme instances there has been complete loss of wer in all four limbs. The sulphonamide neuritis as originally described as a rare toxic effect of sulph- nilamide, usually after considerable overdosage, e amount given ranging from 50 to as much as 30 g. With the development of the sulphanilamide erivatives, particularly *p*-aminobenzenesulphon- limethylamide, case-reports have been fairly fre- quent, and total amounts of only 12–30 g. of this ompound have caused the trouble. The ætiology of the neuritis is not fully understood, but experiments in pigeons have shown that vitamin B_1 will prevent paralysis, and in patients undergoing sulphonamide therapy there is a decreased excretion of vitamin B_1. Unfortunately treatment of the neuritis with vitamin B_1 is only partly successful. All that can be done is to stop the drug and rest the affected parts by splinting until the acute phase has subsided. When there are signs of returning activity steadily increasing faradism with remedial exercises should be given. In severe cases recovery is slow but the ultimate prognosis is still good.

[7] *Edinb med J* 1941 48, 36

The pathology of the lesions has not been adequately studied in the human subject—facilities are happily rare—but much has been learnt from animal experiment. Chickens are peculiarly liable to develop lesions of the C.N.S. under sulphonamide therapy, and in them **Bieter** and his colleagues [1] of Minneapolis have lately demonstrated myelin condensation with axon swelling from this cause. Sulphanilamide was found to be the least harmful to the C.N.S. of the drugs studied, the order of increasing toxicity being then sulphapyridine, sulphathiazole and sulphamethylthiazole. It has been generally supposed that the sulphonamides permeate evenly throughout the body tissues and fluids, with the exception of the cerebrospinal fluid,[2] but in the chickens it was possible to demonstrate selective variations in the concentration of different compounds in different parts of the C.N.S. after treatment, and similar variations are probable in man. The human sciatic nerve may certainly show concentrations appreciably higher than those found at the same time in the blood, and if this is representative of other peripheral nerves the mechanism of the neuritis becomes understandable. The importance of the selective distribution of sulphonamides between blood-cells and plasma has lately been pointed out,[3] and a study of the distribution in other organs seems worth attempting.

Two groups of patients deserve special mention. One is the small group, becoming smaller with improved technique, in whom an acute meningitis follows ntrathecal medication. Thus, disastrous results have ollowed the intrathecal use of the highly alkaline odium salt of sulphapyridine, and paralysis of the auda equina with slow recovery, has been reported after other soluble compounds used in this way. The other group includes the injuries to the gluteal or sciatic nerve, particularly its external popliteal division, after careless intramuscular injections of sodium sulphapyridine, which may produce local necrosis; for this reason it is unwise to give more than 1 g. in 33⅓% solution into the buttock at any one time. If more must be given, it should be given intravenously.

Mental disturbance more pronounced than that commonly arising during acute fevers may be observed during sulphonamide therapy [4] and may be a sign of overdosage. An extreme example of this was in the patient who through an oversight received 4 g. of sulphapyridine four-hourly for three days and developed acute mania. He recovered both mentally and physically on withdrawal of the drug. Less severe examples of confusion are sometimes seen after such moderate dosage that it seems that these patients are peculiarly sensitive. The chances of this complication, like others, is increased if the drugs are taken when up and about, a practice which cannot be too often condemned. Apart from such indiscretions, however, there is a peculiar form of delayed cerebral depression which may follow any of the compounds now in common use,[5] though it was originally described in connexion with sulphanilamide. The depression is characterised by inability to concentrate or add up simple sums, with loss of the fine coordinating power necessary for performing acts like typing. The final prognosis of this is good but it can be very trying while it lasts. There is no special treatment, but the amide of nicotinic acid might be worth a trial.

THE ALLERGIC DONOR

Loveless [6] of Cornell has lately described three cases in which hypersensitiveness, lasting several weeks, was transferred to patients transfused from pollen-sensitive donors. If a transfusion of blood or plasma saves the patient's life it may seem of small moment if the penalty is a brief inability to tolerate pollen clouds, egg diet or some other common antigen, but such transference may have other implications. It is not such a rare experience to meet severe transfusion reaction inexplicable on any grounds other than the anaphylactic, and standard works on blood-transfusion warn us against the allergic donor, although they give us no very definite information as to what happens if we neglect their advice.

That the hypersensitive state can be transferred by serum injection has been known for many years. **Longcope** and **Rackemann** found, for example, that a guineapig receiving serum from a patient with serum sickness itself became slowly hypersensitive to horse serum. **Ramirez** described a first attack of asthma in a man when he entered a horse-drawn vehicle two weeks after being transfused from a horse-sensitive donor. **Mills** and **Schiff**, using a horse-sensitive donor, noticed that an area of the recipient's skin, injected with horse serum some time before the transfusion, did not at once react but gradually developed urticaria two hours later. **Frugoni** described the injection of serum from a woman suffering from rabbit-hair asthma into a normal child who subsequently developed acute conjunctivitis and rhinitis whenever brought into contact with rabbits.

[6] Loveless, M. H. *J. Immunol.* May, 1941, p. 15.

Moreover, there is the evidence of the now classical Prausnitz-Kustner reaction Here if serum from someone hypersensitive to a particular protein is injected locally into the skin of a normal person, the injected area reacts to the same protein **Loveless**, by observing and testing the reactions of her patients over several weeks, now gives the phenomenon practical application She finds that specific hypersensitiveness is definitely transferable by a single full transfusion and that if the patient receives a second transfusion from a donor affected by the same antigen there may be a severe generalised reaction The same thing can happen, of course if the same hypersensitive donor is used twice She confirmed the nature of the changes in the recipients not only by the usual cutaneous and ophthalmic tests but also by actual titration of the antibody content of their sera at the various stages Sensitisation took place only gradually, its appearance coinciding with the disappearance of the injected antibodies from the circulation This sequence is in accord with the current explanation of the mechanism of anaphylactic and allergic phenomena in general It may at first sight seem strange that a sensitivity, seen in man usually as relatively local reactions, can reside in or at least be transferred by the circulating blood, but long ago **Schultz** proved more or less conclusively that anaphylactic reactions all take place in or on tissue cells Later **Dale** showed that living cells slowly take up antibodies whenever these appear in the serum surrounding them, they then become hypersensitive to the corresponding antigen unless the serum still contains so much antibody that it can, by combining with any newly arriving antigen, screen the cells and so prevent the actual antigen-antibody neutralisation from ever taking place in them Subsequently **Lewis** and **Grant** demonstrated that when antigen-antibody neutralisation does take place a histamine-like substance is produced, and, if the site is cellular, gross local stimulation is produced—the local allergic reaction Antibodies conveyed to transfused patients in an allergic donor's blood may be slowly taken up by their cells, and as the process becomes complete the protecting screen of freely circulating antibody grows weaker and the cellular hypersensitive state may supervene

In accepting donors, the inquiry as to allergy should therefore be reasonably serious How often it is so under present conditions is open to doubt, and admittedly when bloods are pooled and antibodies diluted the risks may be negligible But there is reason for especial care when repeated transfusions from a donor are likely to be needed This phenomenon explains the urticarial reactions often seen among repeatedly transfused patients in the days before the blood-banks, when donors from a small series of relatives or those of the less common groups in a small panel often had to be used more than once for the same patient In view of the frequency of the condition, a certain number of donors are sure to be mild unsuspected allergics and although the enormous size of modern panels must reduce to a minimum the chance that blood from any particular donor will be used twice for the same patient, yet the same cannot be said of two donors happening to be hypersensitive to the same antigen The risk may be small but we have no right to ignore it

Annotations

MEDICAL ASSIZES

It is reported in the lay press that the Shake Committee is on tour during August in four groups order to ascertain by local inquiry whether the imm medical man power of this country is being used to best possible advantage The tour is probably a f although none of the fourteen distinguished member the committee is likely to give away any secrets that for one very good reason If their work were j to make a census of an existing situation it would quite simple and there would be no harm in keeping log But the committee men are no mere enumerators they are assessors with judicial minds and sympathetic outlook The equation which they have to solve is not a quadratic to determine *x* but a simultaneous equation with several unknowns and a host of solutions Excessive demands, if such there be, may well fade away before their impact, or even in anticipation of it It may be relevant to note a parallel assize in Australia which led to the cablegram from Major-General F A Maguire to Dr Anderson that no Australian medical men can be spared for service in Great Britain or India There is a pool of 6000–7000 qualified men and women in the Commonwealth it is curious that the number cannot be stated within a thousand or so[1] Of these, 757 are already serving with Army, Navy or Air Force and 286 more have been asked for before the end of the year, the choice is small because the pool is reduced by certain categories which are not eligible—500 women, a like number in essential services, 250 unfit, 1170 males over sixty An eventual field mobilisation of seven divisions would absorb a medical personnel of 1260, leaving no more than 2280 to care for a civil *population* of seven millions—a *median of 1 to 3 100*, and it must be remembered that a large *part* of general practice is in "one man towns" of three thousand or less Th makes it easier *to* understand how it is that of recent graduates with one year's hospital experience only 11 have offered their services, along with 300 older men and 346 specialists The Shakespeare Committee may well feel their task is easier than that of the Australian Coördina tion Committee, and take encouragement therefrom

A SNAG ABOUT BROAD BEANS

The broad bean (*Vicia faba*), being a valuable source of protein, deserves its place in every allotment scheme although we must forgo its traditional complement of pre-Woolton days—boiled ham In Italy it is called "fava" bean and in that country a curious disease affecting the red blood-cells has been known for many years to be connected with eating the beans or inhaling the pollen of the flowers The disease is called favism, and Luisada[2] has lately recalled what is known of it It is seen most often in Sardinia, where thousands of cases occur every year, but it also arises in other districts of Italy and in Greece and North Africa It seems to be limited to people with a Mediterranean ancestry, and this is also true of the cases reported in the United States Where large fields of fava beans are in flower susceptible people may be affected by the pollen, but favism is most commonly caused by eating raw or incompletely cooked beans, or, more rarely, cooked dried beans The symptoms come on 5–24 hours after ingestion, at first they are not striking—chill, backache, pallor and vomiting—but after about 30 hours the two specific symptoms of hæmoglobinuria and jaundice appear The urine varies in colour from red to black, it contains oxy- and met-hæmoglobin and later much urobilin The jaundice deepens rapidly and is often very intense Liver and spleen are enlarged, there i rregular fever reaching 101–103° F The skin is not y yellow but pale, and according to Luisada elops a typical pale-green colour, itching is absent rrhœa is frequent and there may be blood in the ols The red blood-cells fall to between 1 and 2 llion per c mm, in young patients the white cells ay rise to 40,000 per c mm, monocytes and eosino-ils are often increased Hæmoglobin and increased lirubin have been reported in the blood-plasma The tack reaches its peak on the 2nd day and may especi-lly in children, be fatal, if this crisis is safely passed e hæmoglobinuria and fever disappear by the 5th or th day the jaundice subsides more slowly and the red lood cells may take as long as a month to recover their ormal level This is the typical attack, but there are ariations ranging from mild attacks showing only eadache, dizziness and diarrhœa, or jaundice without hæmoglobinuria to very severe attacks described as comatose, hæmorrhagic lightning-like or anuric An urticarial form has also been noted Treatment of the hæmolytic attacks is important since life may be in danger Blood-transfusions have been given successfully, adrenaline intramuscularly and calcium gluconate intravenously are useful After the attack iron should be given in adequate doses for some time, liver treatment is not needed Prevention can at least partly be attained by thoroughly cooking the beans The history and course of the disease strongly suggests that an allergic hypersensitivity to broad-bean proteins is the cause Skin tests with extracts of various parts of the plant gave positive results a few weeks after the attack in all patients tried, but never during an attack Extract of cooked seeds usually gave a negative reaction in patients reacting positively to raw seeds, extracts of dried seeds were generally positive Sensitisation can appear at any age Desensitisation occurs during, and for a short time after, an attack After several attacks some patients develop complete immunity, and in most they become less severe as the patient grows older These findings all confirm the allergic nature of the disease Allergic hæmolysis is unusual and has interesting implications—Widal and the French school for instance, thought that some cases of paroxysmal hæmoglobinuria were allergic—but here we are chiefly concerned to remind doctors in England of the existence of the disease, especially since we are told that people of Mediterannean ancestry will soon be labouring among us, and broad beans are still plentiful

PREVENTION OF NEONATAL HÆMORRHAGE

THE relationship between a low level of prothrombin in the blood of newborn babies and the tendency to hæmorrhage is now accepted and the fact that the administration of vitamin K or its chemical analogue either to the mother or baby will prevent the development of the hypoprothrombinæmia is also established The practical application of these facts in the prevention of neonatal hæmorrhage has now been made by Beck Taylor and Colburn[1] of Brooklyn They gave 2 mg of 2 methyl-1 4 naphthoquinone to alternate mothers in a series of 2059 cases Of these 1037 were used as controls and 1022 received vitamin K Because some of the patients were too far advanced in labour at the time of admission to be of value in the vitamin-K study, the control group contained 15 more cases than the vitamin-K group The drug was given during labour, at least an hour before delivery The results showed that in the control group 21 cases or 2%, showed evidence of hæmorrhage, whereas in the vitamin K group only 5, or 0 5%, showed any signs of bleeding In this series prophylactic vitamin K thus seemed to reduce the incidence of hæmorrhage in the newborn by about 75% The Brooklyn workers suggest that the results might be improved still further by adopting their present programme which is to give 2 mg of vitamin-K analogue at the time of admission and repeat the dose every 6 hours during labour In cases of premature labour they propose to repeat the drug every 4 hours Detailed analysis of the results obtain in this study however, reveals several difficulties For example, the crude "bleeding rate" for the Brooklyn control babies put at 2%, compares unfavourably with a series reported in this country by Capon,[2] where the incidence in 19 421 live births in the Liverpool Maternity Hospital was 1 in 405 This point was, in fact, made in a discussion of the Brooklyn paper and Dr Beck's reply suggested that the high incidence might be explained on the grounds that a large proportion of the hospital patients came from a low economic group where dietary deficiency was likely to be present He thought also that this dietary defect might account for a different incidence in private and hospital practice, although he gave no figures to support this view. Another possible explanation for the disparity is suggested by the fact that out of the 21 control babies who bled, 14 are listed as suffering from intracranial hæmorrhage and 7 from blood in the stools In the treated series of 5 babies showing evidence of bleeding 4 are recorded as having intracranial hæmorrhage and only 1 with blood in the stools Thus prophylactic vitamin K reduced the incidence of melæna neonatorum from approximately 0 7% to 0 1%, whereas for intracranial hæmorrhage where the additional factor of trauma must play an important part, the reduction was only from 1 4% to 0,4% It is not made clear whether or not the diagnosis of intracranial hæmorrhage was confirmed at autopsy in every instance, and every case of intracranial hæmorrhage cannot of course be attributed to hypoprothrombinæmia alone Indeed since every infant is now known to pass through a stage of hypoprothrombinæmia after birth some other factor must also be concerned with the production of hæmorrhage in a relatively small proportion of cases Prophylactic vitamin K seems well worth giving as a routine but it will not excuse the obstetricians from seeking to prevent trauma and premature delivery The forces of nature cannot always be blamed for trauma and the fact that intracranial hæmorrhage may occur after delivery by cæsarean section is shown by the case recorded by Dr Lapage in this issue The factor of asphyxia as a contributory cause of bleeding in the newborn may require more emphasis and asphyxia is unfortunately not uncommon among infants born by the cæsarean route Oxygen, gentle handling and prophylactic vitamin K form an important trinity in preventing neonatal hæmorrhage but growing enthusiasm for the last must not lead to the other measures being overlooked

LONDON INQUESTS IN 1940

THE agenda of the London County Council included last week a report from its public control committee covering the work of London coroners in 1940 More deaths were reported than in the previous year (10 129 against 9158), but fewer inquests were held (2979 against 3172) The exercise of the trusted discretionary powers of coroners is further shown by the statistics of post-mortem examinations These were directed to be made in nearly 90 per cent of the inquest cases and in 77 per cent of the cases where it was held that no public inquiry was necessary The report makes no specific mention of war time conditions The coroner's jurisdiction has, of course been partially excluded by Defence Regulation 30 This temporary law enables local authorities to inter the bodies of persons who die in consequence of war operations "notwithstanding anything in any Act," and in relation to such interments suspends the section of the Births and Deaths Registration Act of 1926 which prescribes that dead bodies are not to be disposed of without either a coroner's order or a registrar's certificate. Regulation 30A, authorising coroners to inquire into deaths caused by war operations and to issue certificates enabling registrars to register the deaths, was not issued till last March and so falls outside the year under review. The total of 538 cases of suicide is fewer by 14 than in 1939, 171 of them were persons over sixty years of age. Deaths due to excessive drinking were 58 against 77 in 1939. Inquests on newly born children fell from 36 to 27, 20 of these cases were found due to want of attention at birth. Lastly in spite of all shifts of population or other changes due to war, the number of verdicts of murder (3) remains the same as in the previous year. The steadiness of murder figures is one of the curiosities of our social statistics and has often attracted comment in the annual reports of the Home Office. That department's volume of criminal statistics for 1940, when at length it is published will give us much fuller information of the work of coroners throughout the country. There is no evidence that their usefulness is decreasing.

FATE OF THE SKIN GRAFT

As in the last war, skin grafts are being done up and down the country and on all fronts in an attempt to cover the raw surface of wounds or burnt areas. These may be considered grafts of emergency, and in them the surgeon will be more concerned about the likeliness of the "take" than he will be about the appearance or function. With more and more knowledge of the bacteriology of wounds, of cleansing methods, local chemotherapy and the prevention of cross infection in wounds, the percentage of takes will increase and the appearance and function of the graft will come in for a greater measure of criticism. In grafting done at leisure a high standard must be expected and attained. Such grafts are required to cover a surface after removing scar tissue or neoplastic tissue or to improve the function of a part. Cole,[1] for example has lately described operations designed to improve the function of damaged hands, and the plastic units are kept busy with such cases today. It is therefore important to learn not only what can be achieved by grafting but also the fate of the grafts so that the patient and surgeon may know what to expect.

Like tissue should as far as possible be replaced with like and for this reason all advantage should be taken of local flaps before considering flaps from a distance or free grafts. Local flaps make the best repair. When skin and deeper tissue are missing pedicled flaps from a distance may be required and such flaps may give a very fine result though the skin tends to remain rather white, especially if the donor area is the abdomen. The skilful use of cosmetics is justified in these cases. Free grafts are liable to fall short of the desired standard. In grafts of emergency where the take may be indifferent, and the recipient area is covered with granulation tissue and fibrous tissue, the graft tends to be stiff, irregular and fixed. The same thing happens if any scar tissue is left under a graft done at leisure: such grafts are liable to break down under the slightest trauma, or merely when placed in a dependent position. But when all scar tissue is removed an even flat surface can be obtained, and it is remarkable how supple such a graft will become with the lapse of time. But some contraction is to be anticipated and the thinner the graft the more the contraction. Pigmentation is also liable to develop in free grafts. Brown and McDowell,[2] have recorded their observations on the fate of grafts in growing people. They show that if the grafts have been satisfactory at the start they enlarge and stretch with the growth of the patient and remain satisfactory. By this they mean that the skin will be enough for free movement, of moderate looseness and able to withstand the usual traumata and will develop normal sensation. If scar tissue is the edges at the time of grafting this will imp result. Grafting on an area of fibrosis such as radiation will either fail in the first instance or surface that cannot withstand trauma. Wrinkl the graft is probably due to failure to remove fine of scar tissue from the raw surface. Blood vessels early on the scene while lymph channels grow in s Œdema below a circular scar may even be cured grafting after removal of the scar. Sensation begins appear in a graft after some months (always pro the cutaneous nerves have not been com destroyed), at first in isolated spots which enlarge and coalesce, while some nerve fibres grow in from the edges. Metaplasia does not occur. A graft to the sole of the foot never becomes as thick as the rest of the sole. Skin replacing mucous membrane or conjunctiva always remains white and secretes sebaceous material, and hair will grow if the graft is cut thick. Grafts to cavities must therefore be cut very thin. Heterogenous graft never survive as such but are either shed or gradually replaced by new tissue. They have an occasional application as a temporary covering during a critical phase and have been used for this purpose in badly burnt children.

REGURGITATION OF TUBERCLE BACILLI FROM THE PHARYNX

THE portal of entry is not a very fashionable subject in the study of tuberculosis nowadays, when everybody is thinking on community lines about large scale infections and mass surveys. A year ago Gloyne[1] reviewed the literature chiefly from the angle of the primary focus and contact infection. Now White and Minett[2] have produced a helpful paper on the pathogenesis of tuberculosis in the calf, which contains facts which may well be translated into terms of childhood infection. Young bull calves from a tuberculin tested herd were used for the experiments, and the tubercle bacilli were introduced by (1) naturally infected raw bulk milk or mixed samples of milk from cows suffering from tuberculous mastitis, fed to the animals by the ordinary bucket method or introduced by stomach pump, (2) culture of bacilli suspended in milk and administered by the teat bucket as used in commercial calf-rearing, (3) intratracheal inoculation of cultures, and (4) injecting cultures suspended in milk into the duodenum by a stomach-tube, or placing them, enclosed in a gelatin capsule, directly into the duodenum by operation under intravenous anæsthesia. Apart from results important from a veterinary point of view, the work of White and Minett is of value in calling attention to primary lung infections by regurgitation from the pharynx. This was clearly demonstrated by the experiments. The teat or bucket feeding of young calves, with their well known propensity for immersing their head in the bucket and splashing the milk throughout the naso pharynx, affords an excellent opportunity for primary throat or aspiration tuberculosis. The Lübeck disaster[3] with the administration by mouth of B C G tubercle vaccine to young infants, whose facility for regurgitation is remarkable, led to similar conclusions. There a virulent strain of tubercle bacillus accidentally gained access to the vaccine, and 77 children died. Primary foci found in the lung and in the middle ear suggested that these areas were probably infected by regurgitation and vomiting after the administration of the vaccine and there seems no reason why natural infection should not take place in this way if feeds of raw milk happen to contain tubercle bacilli, as they must often do. Cobbett raised this possibility many years ago in his criticism lmette s experiments on animals which were made pport of the intestinal route of infection He es one series of experiments on goats, animals rally possessed of a good resistance to tuberculosis, hich Calmette failed to produce tuberculosis when the rcle bacilli were fed to the goats in enormous quanti- between slices of bread but succeeded in producing erculosis of the lungs without obvious involvement the mesenteric glands when the bacilli were ad- nistered with an œsophageal tube Cobbett's chapter the portal of entry in his classical textbook,[1] written 1917, is well worth reading today It is an odd thing out the battles of long ago that they are so often ight all over again by the next generation The ntroversy on the portal of entry seemed to be closed, d regurgitation from the pharynx was a mere " snag " the experiments Now the evidence of the Lübeck saster with infants, supported by White and Minett's periments in calves, suggests that the regurgitation infected raw milk may be a common route of infection acute pulmonary tuberculosis of infancy and childhood

SELECTIVE TESTING FOR THE ARMY

IN a recent leading article (July 26) some account was iven of what is being done in the United States of merica to assess the mental fitness of army recruits ention was then made of a call for men and women ith psychological training to enlist in the British Army or the purpose of selecting personnel We understand hat a system of selective testing is being introduced esigned not to estimate a man's mental fitness from the nedical point of view, but to assess, so far as this is ossible by testing, a man's latent qualities with a view o employing him in the job for which he appears to be nost suited The object of the scheme is to ensure that he best use is made of our man-power and that the right nan is employed on the right job A Directorate of election of Personnel has been set up in the War ffice to organise the scheme

TRANSMISSION OF YELLOW FEVER

BELIEVING that the important work of his father in lucidating the mosquito transmission of yellow fever as been largely ignored in English-speaking countries, rof Carlos E Finlay has with filial piety produced an xtremely interesting book[2] to rectify this apparent eglect In 1881, some years before the discoveries of anson and Ross in malaria, Carlos Finlay had already romulgated his theory of the transmission of yellow ever and had successfully pointed out the guilty o-quito, *Aedes ægypti* In 1894 Finlay read a paper hich laid down the measures necessary to prevent the pread of yellow fever These measures were in all ssentials those employed by Gorgas in his successful ampaign to eradicate yellow fever from Havana For wenty years Finlay with unabated patience preached to credulous world the doctrine of the mosquito trans ission of yellow fever , his incentive it was that caused he American commission to investigate and finally to rove the rôle of mosquitoes in transmission Such are inlay s titles to a fame which will last as long as tropical edicine endures But when it comes to Finlay s fforts to prove his theory it is another story It is now greed that after the bite of an infected mosquito the cubation period in man is 2–6 days , that after the hird day of fever the virus can no longer be obtained om the circulating blood since it is neutralised by mmune bodies , that after taking an infective meal an extrinsic incubation period occurs in the mosquito which even in a tropical climate is not shorter than 8 days that it is impossible to diagnose yellow fever clinically, and once a person has had an attack of yellow fever he will not again contract the disease Finlay made 102 attempts to infect human volunteers with yellow fever by the bites of presumably infected mosquitoes In only one instance did 7 days elapse between the time that the mosquito had taken its infective meal and the time that it fed on the volunteer ; the extrinsic incubation period was therefore too short In 4 cases only did the mosquito feed on a patient with yellow fever on the second day of the illness and in only 17 cases on the third day of illness The incubation period varied from 5 to 27 days in only 4 instances being under 6 days while of 16 patients who showed symptoms following a supposed infective bite 5 are reported to have had second attacks. None of the 102 volunteers died of yellow fever, the diagnosis of infection being based on clinical grounds in every case It is therefore hardly surprising if Finlay s experimental proof of his theory has failed to carry complete conviction

THE MIDWIFE WHO PRACTISES

ON April 1 there were 64 440 names on the roll of midwives or 854 more than the roll has ever contained before The Central Midwives Board, which provides this information but cannot publish it for lack of paper, gives the date as March 31 , but in view of the fact that more than three-quarters of the enrolled women have no intention of practising as midwives the overnight date seems more fitting Of some 16,000 women who enrolled in the 5-year period 1935–39, just before the new rules came into force, only 28% gave notice of intention to practise during 1940 Of course the old rules were largely to blame, for the board's certificate had come to be tacitly recognised as an academic diploma, honourable indeed but carrying no obligation Under the new rules only the pupil-midwife is likely to take the second period of training which qualifies for the full certificate and gradually the roll will become a real list of practitioners This real list last year had 15,874 names 1347 less than in the previous year, and 1620 less than the peak year of 1937 when the need for midwives was so much smaller that many of the less efficient could safely be pensioned off Let it be noted, however, with thankfulness that at the second (and final) examination last year 818 of the 948 candidates were successful , despite overheads the board s programme of examination was carried through according to plan Encouraging also is the willingness last year of 202 women to resume the practice which they had seen fit to lay down, whether from age or domestic ties A reflexion of the latter appears in a special ruling of the board in response to inquiry that a midwife must remove her wedding ring while attending a confinement

Awards to Medical Men —The D S C has been awarded to Surgeon Lieutenant G L Ward, M B Camb , R N V R , for bravery in the Battle of Cape Matapan The M B E has been awarded to Dr William Remington of Woolwich for brave conduct in civil defence

Pension for Naval Officer —Surgeon Captain P M May, M R C S , R N retd , has been awarded a Greenwich Hospital pension of £50 a year in place of Fleet Surgeon C S Facey who died on June 20

Medical Prisoners of War —In a recent casualty list the following R A M C officers are posted as prisoners of war W S ,Captain Graham Forrest Hay M R C S W S Captain G B Leyton M B Camb Captain G R Mackay, M B Aberd , W S ,Captain J G Munro, M B Aberd , W S ,Captain Kenneth Todd, M B Manc and Captain H W Wykes M R C S The *Yorkshire Post* states that Captain W G France who was reported missing in June is now known to be a prisoner of war

In England Now

A Running Commentary by Peripatetic Correspondents

DURING an April blitz on London I took a letter to the post. Big, almost stationary, flares lit up the sky, flack-fire was like twinkling stars, the dogs of war barked hungrily. At the corner of the street watching it was a group of youths and girls. Their voices had the ring of casual conversation, with the sound of rejoinder and snatches of laughter. My mind went back to Mr. Wells's film "The Shape of Things to Come" with its terrified stampeding crowds. Well, it has not turned out like that at all, but all the same it was an amusing film. Most of us have these penetrating yet inaccurate glimpses into the future—mine come specially when I have a little alcohol. A sherry? Well, thank you, I don't mind if I do. My thoughts are at first soberly pharmaceutical as I gaze into the medical future. In the very foreground I see Tab. sulphapyridine co. (osonin, Dover's powder and sulphapyridine), Gargarisma sulphanilamide, Ung. derris co., Tab. sulphathiazole cum vitamins A-Z. Nothing very startling in those. This one's on me. I don't think medicine has used ordinary mechanics enough. Take the centrifuge for instance. That case of dropsy of the legs could easily ... Yes, Nurse, with legs towards the centre, of course. Quite comfortable? Right you are. Whirr. What's this case? Difficult labour? Certainly. We'll want the nets up for this, Nurse. Whirr. Or a mechanical heart which can fixate a limb and put an endless chain of mechanical strokers down the course of the main arteries, while another series of coaxers run up the main veins. What's this, Nurse? A pneumonia. Heart flagging, what? Oh well, adjust a M.H. to his left arm and right leg and give him—well, perhaps just one more. One always comes down to politics in the end, doesn't one? Have you seen that order from the Medical Gauleiter, the one about in the future there's to be no such disease as diabetes, because it is so common among non-Aryans? What's it mean? What, don't you know? Well, this is strictly between you and me and the G.P. The real reason is that the Pharmacy Gauleiter has made a corner in insulin and the M.G. who loathes him like pink poison is getting his own back. Have another. Beastly, that sort of thing, isn't it? Still I'd rather have that than the old laisser-faire methods of the degen. democs. They say they have got chain doctors there now. Chap called McJoseph. Hundreds of assistants everywhere, all have to take his name by deed poll. Poor old G.M.C. can't do a thing. Front doors scarlet with green R.A.M.C. snakes, like Woolworths. Red lights twinkling outside, electric signs "Midwifery, a speciality," "Surgery for sixpence." Dreadful state of affairs. Why ... "Time, gentlemen, please." Quite.

* * *

The fathers' match this year lacked something of its accustomed glamour, but the headmaster assured us beforehand that the boys had had a thoroughly bad season so we looked forward to putting up a fair show and perhaps even winning for once in a way. The boys batted first and their innings was noteworthy for the vigour and ferocity with which they attacked the bowling, the number of catches dropped and the lamentable lack of agility in the field. The first wicket fell at 40 and, to cut a long story short, the little squirts had the colossal crust to declare at tea-time with the score at 200 for 5. I bowled my guts out (metaphorically speaking) for two costly wickets. Tea, if less lavish than in past years, was adequate and bulky. The fathers started briskly by losing 3 wickets for 10. Going in myself about number six to stop the rot, I failed to stop a rather straight one that shattered my castle. When I left to take evening surgery we were still 70 behind with only three very unreliable wickets still to fall. I bet we lost again. [Later. We did.]

* * *

Coupon woes are not confined to the females of our hospital staff. It is true that such matters as the supply of white coats assume added importance when the articles have to be paid for in margarine as well as money, but the thing goes further than that and has introduced to our hermit-like existence yet another touch of simplicity, compelling the formerly re rather plethoric members of our brotherhood to things which they would not otherwise have Darning and the execution of miscellaneous have come into their own, and those who were discard are now compelled to renovate and Suits that had long been consigned to the forgotten things, or written off in terms of some have been turned out to render further service the most devastating effects of the new economy their insistence on a policy of repair. Some of colleagues are evincing a new interest in medicine, learning again that a stitch in time nine, and there is something homely and uns —if unusual—in the sight of sober surgeons with the intricacies of torn shirts, holey socks refractory buttons. The new order promises to a new pride in craftsmanship, Surgeon vying Anæsthetist, and General Duties contending with

The Surgeon's socks are his chief woes. They The Surgeon is tall, and if his socks shrink in both they become difficult to pull on in the first instance, even then irksome and restrictive. On more than one occasion he has been delayed by fierce battles with his socks well into the forenoon, and things have come to such a pass that he has taken to washing his own socks rather than let them take their chance in the laundry. Occasionally a maid, stumbling on his secret treasure, sends some of his possessions to the laundry unbeknown to him, and a mistake of this sort is inevitably be-et with unhappy consequences. The Surgeon has recently been practising some species of tension relieving incision, which will restore to circulation socks that seemed to have assumed irretrievably the atrophy of age, and he has borrowed from his theatre a dilator sometimes used for other purposes but now making heroic efforts to stretch again his abbreviated woollens. Nor are these stocking woes confined to the Surgeon. The Anæsthetist has them, too, but his are not so much the pains of contraction as the inherent pains of holeyness. He has taken to darning his own socks, and the process is successful in so far as it obliterates empty spaces, but it substitutes great hard lumps of tightly drawn thread that suggest some loathsome disease, and at the same time produce on his unhappy soles alternate corns and calluses that have driven him to wear broad nosed shoes, serving to accentuate his already lugubrious tread. He, too, has evolved a darning technique, and of an evening can be heard in his corner mumbling some ancient rites ("one, two, three, four"), related to the work in hand.

General Duties has lived in the East, and in the back woods has had to fend for himself. He has immense faith in his ability to sew on buttons in a way that ensure their permanent anchorage. "Give me needle and thread," is his motto, "and I shall sew them on," and they seem to stay on as if fixed in place by terrific hawsers as everlasting as the world itself. He airily spurns all offers of feminine assistance in these rehabilitative pursuits, preferring to stand firmly on his own feet, though some of his lady colleagues, and even some of our students, have offered to tie him together, all he will have from them is the loan of their needles and thread. Not all of his professional brethren share his self-sufficiency. Most of them have ward sisters somewhere who will, for a consideration (unspecified), do what is necessary to preserve their patrons in a state respectability and comfort. The sewing on of butto and the darning of socks is regarded by some of unprincipled, if prudent, ones as a part of ward like the making of 11 o'clock tea, which seems rather hard on the noble spirits who try to do their own There has recently been some discussion as to the welfare officer in such a hospital as ours ought to a male or a female, and arguments have been put in support of each belief, but surely in this the welfare of the medical staff is an important that has been overlooked. Since the medical staff predominantly male, it seems clear that the welf officer should be a lady—a lady possessed not of tact and perseverance and all those other qualit that go to make up the ordinary conception of an welfare officer, but possessed also of those dome s without which no residency is bliss and without none of our male colleagues can be expected to f their best in these exacting days

* * *

king to the push-bicycle again after an interval of a e of decades or so I find that I no longer get the thrill as I used to out of riding down steep hills defective brakes , I like to be able to stop the thing leads me to wonder why as we grow older so many , tend to put a higher price on our heads That we ld take increasing care of our vile bodies at a time of when we are intrinsically less valuable to the com-uty doesn't seem reasonable My second profound ction is that the modern so-called super-sports are less comfortable to ride than the old upright models ill grudgingly concede that, bent low over drooping dlebars, the rider offers less resistance to the wind, surely when each time he bends his knee he strikes iself a powerful blow in the abdomen, he is working a mechanical disadvantage But perhaps I am no ger worthy to be called a super-sportsman

* * *

Some time ago I had occasion to speak in these lumns about my hens Of the original 18 there are 15 rvivors still filling on an average 6 shells a day Dopey id to go, she was a nice bird but slow off the mark and ioroughly hen-pecked Moreover there was convincing idence that she wasn't pulling her weight in the factory bsenteeism from the laying box is little short of treason iese days, so we ate her Knowing her so intimately it as hard for any of us to administer the coup de grâce, ut a billeted soldier twisted her neck neatly and without ompunction, and there's no denying that she was good n the table Among the newcomers to the hennery re 6 half-grown light Sussex pullets and a cockerel, hich are veritable Nazis among poultry They bully all naller birds and are constantly seeking fresh lebensraum f the french windows are inadvertently left open the ght Sussex instantly occupy the drawing-room carpet r the dining-room table, when ejected they look idignant I am looking forward to eating that cockerel ho is nothing more nor less than a fuhrer on a slightly naller scale Recent additions to our fauna include a osling and two young nanny goats Gertie the gosling very young indeed, but takes kindly to a diet of clover nd water and we already say "Boo" to her The annies, Syrene and All-cleara by name, were carried in y two small girls of about the same size We under-and that their staple diet is nettles with an occasional .R P memorandum as a special treat

* * *

There are subtle slight changes going on in our daily fe that lead on to others which at first sight may seem nconnected Thus the O P sister has encountered a ew minor anxiety in patients fainting in the dispensary ueue They had all been to the throat department nd had all had their noses cocainised We have always een on the lookout for the patient who in the hands of n extravagant dresser faints in the examination room, ut this was a new one Sister discovered that they ad all come up without breakfast Difficulties in avelling are bringing many people up to London ithout any This is reflected in the crowds at the yons shops at 8 30 A M If you catch a 7 A M green-ne bus it is really 5 A M and even in these hot days ou will be cold on arrival So those that go in for a arming cup of coffee are added to those who habitually reakfast there But these are not all There are ose who have been on duty all night and come in for meal when going off duty And so the marble tops ave a busy time Shortage of starch and material as changed the Nippy's costumes The white caps nd aprons over the black uniform have gone A black eaked cap and overall has replaced them This means at the girls have now to provide their own dresses nd it means that the customers can observe their rearms It has always been recognised that a man a right and even a duty to look at a girl's feet and nkles before judging her character I learnt this from father The old man would settle after dinner in e arm-chair, in which I now doze on Sunday after-oons, and there suck at his pipe and read his book rvant my mother was all agog to know his opinion and hardly had the dining-room door closed upon her before she would say, 'Well Tom ! what do you think of the new girl ?" 'Humph' the old man would say, "She'll do Her ankles are tidy," and then would return to his pipe and his book Acting on this paternal education I have always held that in selecting a nurse for the operating theatre we should pick one with neat ankles and feet and one who can fit up a nasal snare while one barks at her But the new Nippy costume has made me realise that whereas ankles are questions of form, forearms and hands are a question of emotion When you watch a Nippy with her bare arms sorting out cups of coffee saucers spoons and an odd lump of sugar or two you can see into her soul In future I shall insist on rolled-up sleeves when the test snare is being prepared Incidentally nurses would be much better off without their stiff cuffs and tight sleeves, and if the little bit of muslin above the elbow that first was characteristic of the London Hospital nurse was made universal

SCOTLAND

WAITING FOR HOSPITAL

Lord Craigmyle is satisfied that emergency hospitals should be used to reduce the long waiting-lists of voluntary hospitals Speaking in aid of the County of Selkirk cripples' aid committee he admitted the need for a reserve of beds to meet a great emergency, but, said he 80 per cent or more of emergency hospital beds could be cleared rapidly at a crisis, patients being no worse off than before A physician in charge of beds at an E M S hospital had told him that his ward could be cleared in two hours But even if it took two days could that excuse the policy of keeping down the number of patients to a bare minimum and of turning the rest away ? He was thinking particularly of that long, pathetic queue of men and women requiring operation who could only be cured in a hospital bed These people were paying for the upkeep of the new hospitals , they were paying the salaries of doctors and nurses who were eating out their hearts in idleness How could we have an efficient hospital system when it was starved of patients, and how could we have an efficient population if it were excluded from the hospitals for which it paid ? He was not criticising the voluntary hospitals ,- the long waiting-lists were no fault of theirs All the same the waiting-lists were a scandal to Scotland Nor did he criticise the Department of Health for Scotland , he knew a little of the laborious days and nights which their officials had been spending since (and indeed before) the war broke out But civil servants, however able were not the makers of policy If the policy were timid and inadequate it was for the central government to define a more humane and a more courageous one The more work the emergency hospitals did, and the stronger the link between them and the voluntary hospitals the better it would be for Scotland now and after the war It was only by keeping the machinery in running order that it would be efficient in an immense crisis, if ever it came

DEATH OF PROF A J CLARK

The Edinburgh faculty has lost one of its most distinguished members by the sudden death on July 30 of Dr A J Clark, professor of materia medica since 1926 when he succeeded the late A R Cushny Professor Clark came to Edinburgh with a distinguished record After taking a first class in the natural sciences tripos in 1907 and qualifying from St Bartholomew's in 1910 he held appointments in pharmacology at King s, University College and Guy's In 1918 he was offered a chair at the University of Capetown, and a year later succeeded Cushny at University College becoming also dean of the medical faculty He succeeded Sir Charles Sherrington as a member of the Medical Research Council in 1931 In the last war he was awarded the M C and he again saw active service for a short time during the present war, being in France and Flanders during the German drive in the spring of 1910 After returning to this country he was seconded for university duties and under his direction active work was in progress in connexion with the war effort His textbook on Applied Pharmacology ran through many editions and became a standard work Professor Clark was known by colleagues and students alike as a rather shy but most approachable man to whom problems could be taken at any time with the assurance of his fullest help In his immediate associates he inspired an affection and respect such as can have been enjoyed by few He took an important part in building up the central medical library in Edinburgh University and in its daily running Of the medical school he came to be an active and integral part Professor Clark is survived by his wife herself unhappily an invalid and by four children, his eldest son being a medical student at the university

INFANT LIFE

In an address at the annual meeting of the Fife Children s Home, Prof Charles McNeil said it was a melancholy fact that in Scotland the infant death-rate was too high The Scottish was now much above the English rate, although forty years ago the reverse was true That meant that England had tackled more successfully the control of the health of her children The problem was how to give all mothers adequate homes along with knowledge of health matters and the will and ability to apply that knowledge Scotland had prided herself on progressiveness in education but if the health of the children was to be improved they would need to revise some of their educational methods To education in reading and writing and adding up figures must be added that final coping-stone—education for life itself

PALESTINE

After last autumn's air-raids, which mainly affected Haifa and Tel-Aviv two meetings were held to discuss the problems which they had raised and the experience we had gained from them It was decided to increase the number of hospital beds available for casualties both in these towns and in the smaller ones, and more operating theatres have also been provided In addition the Jewish Red Cross have erected many stations for giving first-aid in raids The public has been instructed by articles in the newspapers, courses of training and so on as to what to do when bombs fall, and a service of blood-donors has been organised In those raids there were a lot of cases of ruptured ear-drum, so the public have been advised to plug their ears with cotton-wool when a raid is on There was, too a good deal of thrombosis following operations performed immediately after the raids, and it has therefore been decided where possible to delay operation until the first shock is over Some of these measures have proved their value in subsequent raids

In March a congress of the Jewish Medical Association of Palestine took place in Tel-Aviv It was well attended by Jewish doctors from all over the country as well as many English and Polish ones One day was taken up wholly with papers in English, and there were some lively discussions, particular interest being shown in the papers by Professor Zondek on the biology of the heavy metals and by Dr Goldberg on the curious allergic disease, favism Allergic diseases are particularly common and severe in Palestine and the Near and Middle East generally, as Wodak has lately pointed out in the Hebrew medical paper, *Refuah* (Medicine), and those which affect the nose are shortly to be the subject of a meeting of Palestine otorhinologists In Haifa a meeting has been held between doctors of the various nationalities in Palestine—Hebrew, Arabic and English—and the government are sponsoring similar meetings aiming to bring together the Hebrew and Arab medical men The few meetings which have so far been held seem to have been successful and the scientific standard has been high,

Shimkin of Haifa has been treating trachoma with sulphanilamide, and reports his results in *Refuah* In 32 severe cases some of them complicated by ulceration, pannus crassus and the like photophobia and blepharospasm disappeared on the second or third day He gives 1 gramme of sulphanilamide three times a day. Rosenbaum and Alper of Tel-Aviv in the same number of *Refuah*, discuss the relation between complexion and susceptibility to colds They have observed dren mostly between the ages of two and five, period of several years, the racial sociologi nutritional conditions being much the same About 80% had a comparatively light colouring of these had more than four colds a year , of the der, with dark complexions, only 20% had mo four colds More of the fairer children than t show enlargement of tonsils and adenoids , pre this is a consequence rather than an explanation greater liability to colds

---

Public Health

From the Annual Reports

EALING

The population of this borough increased from 11 in 1931 to 164,400 in mid 1939 At the census t were 26,700 structurally separate dwellings , in 1 the rate-books showed this number to have increased 46 000 House density therefore diminished from 4 3 3 5 The birth-rate in 1939 was 14 8, the infant mortality rate 48 and the general death-rate 9 5 Th are about average for the past few years A notable point in the death table is the rise in suicides from 8 in 1938 to 26 in 1939 No case of cerebrospinal fever was notified in the borough during the year Dr Or reports that a scheme was drawn up whereby municipal midwives could assist at the Perivale Maternity Hospital or the staff at the hospital could assist the municipal midwives in any emergency This is a system which many boroughs favour, but of which the Ministry of Health does not approve

HAMMERSMITH

In 1911 the infantile mortality of Hammersmith wa 146 , in 1939 it had sunk to 43 Since 1924 the general death-rate of the borough has remained fairly constant the lowest rate in the period being 11 4 in 1928 and the highest 13 in 1927 In 1939 it was 12, about the averag for the 16 years Dr Howell in his report gives a table of deaths from cancer in the ten years 1930–39 Th average yearly toll was 227, a number recorded in 193 and 1939 This table shows a fairly constant death roll but a remarkable difference in its age-distribution, the most interesting features of which are a great reduction of persons aged 25–35 and an even more significant reduction in those aged 45–55 In 1930 cancer killed 99 persons in this latter age-group, in 1937 it killed 5 in 1938 only 41 and in 1939 only 29 Another favourable feature is the reduction of maternal mortality from in 1925 to 1 in 1939 Here substantial reduction started in 1935 In the first five years of the period the average was 3 9 , in the second five, 4 1 , and in the third five 1 2

DERBYSHIRE

Dr W M Ash's report for 1939 is cut to the bone but he gives a full account of an action brought again the county council under the Midwives Act of 193 which imposes on authorities the duty of supplying a adequate number of domiciliary midwives The inciden was the usual one of no midwife being obtained whe wanted in an emergency, but the case is importan because the county court judge found "The statut discloses no intention to give private right of action i addition to the remedies provided in case of failure '

SHEFFIELD

Dr H M Cohen gives tables of the average height and weights of Sheffield children in elementary an secondary schools in 1920, 1928 and in each of the p four years, with the Board of Education standard (1928 for comparison These show, as do all such table for all parts of Britain, that in both sexes and at a ages the heights and weights of children have increa regularly during the past 20 years, the only appar exceptions being in groups in which the numbers a too small for the results to be significant Speaking lousy heads, Dr Cohen makes the important stateme (founded on findings) that though children cleansed as a rule found to be re-infested on subsequent exami tion, evacuated children found lousy on reception a cleansed have remained clean

connexion with the war effort His textbook on Applied Pharmacology ran through many editions and became a standard work Professor Clark was known by colleagues and students alike as a rather shy but most approachable man to whom problems could be taken at any time with the assurance of his fullest help In his immediate associates he inspired an affection and respect such as can have been enjoyed by few He took an important part in building up the central medical library in Edinburgh University and in its daily running Of the medical school he came to be an active and integral part Professor Clark is survived by his wife, herself unhappily an invalid and by four children, his eldest son being a medical student at the university

DERBYSHIRE

Dr W M Ash's report for 1939 is cut to the bon but he gives a full account of an action brought agai the county council under the Midwives Act of 193 which imposes on authorities the duty of supplying adequate number of domiciliary midwives The incide was the usual one of no midwife being obtained wh wanted in an emergency, but the case is importa because the county court judge found "The statu discloses no intention to give private right of action addition to the remedies provided in case of failure"

SHEFFIELD

Dr H M Cohen gives tables of the average heig and weights of Sheffield children in elementary a secondary schools in 1920, 1928 and in each of the p four years, with the Board of Education standard 1928 for comparison These show, as do all such tab for all parts of Britain, that in both sexes and at ages the heights and weights of children have incre regularly during the past 20 years, the only appar exceptions being in groups in which the numbers too small for the results to be significant Speakin lousy heads, Dr Cohen makes the important statem (founded on findings) that though children cleansed as a rule found to be re-infested on subsequent exami tion, evacuated children found lousy on reception cleansed have remained clean of an apparently lifeless newborn baby after an muscular injection of 0 5 c cm had produced no onse It subsequently struck me that this dose of azol should really be enough to produce convulsions n infant, and I was interested to learn a few weeks from a fellow practitioner that a second injection of c cm of cardiazol-ephedrine, given to an infant 15 old in a state of collapse after a first 0 5 c cm had red ineffective, had been followed immediately by ulsions which continued till death supervened two rs later Thus it seems quite possible that babies t do not breathe may require some exaltation of cere-l sensitivity bordering on the convulsive to sensitise m sufficiently to their cutaneous stimulation to start iration When the brain has started functioning ively after birth such a dose may actually cause vulsions This is hypothetical but it fits in with Joseph Barcroft s experimental work and has real ictical importance I am interested to note (*Practi-ner* July, 1941, p 429) that strychnine hydrochloride still recommended for asphyxia neonatorum The se suggested (gr 1/300) seems ample for a baby, but view of the above reasoning it might be justifiable to an even larger dose if that failed I may perhaps so refer in this connexion to my letter on drowning *rit med J* 1940, 1, 1035)

Winsford, Cheshire W N LEAK

SANDFLY FEVER

SIR —Your leading article of Aug 2 recalled a study made in Baghdad on the blood-picture in sandfly fever *rans R Soc trop Med Hyg* 1937, 30, 309) A series of 30 cases were investigated They showed a neutropenia nd monocytosis, and the eosinophils reduced to less han half the normal figure A striking characteristic f the white cells was the large proportion which showed egenerative changes Smear and basket cells were ommon, the granulation of many neutrophils was eficient and even absent, and numbers of monocytes ere vacuolated or had pale, diffuse cytoplasm and lightly aining nuclei, and the chromatin network had a ashed out appearance Even more striking was the xtremely low polynuclear index—i e, the Arneth count s modified by Cooke and Ponder The deviation was the ost "left-handed" of any blood-picture met with in aq This proved a useful point in the differentiation etween sandfly fever and malaria Numbers of meta-yelocytes and other "abnormal" leucocytes were found the original paper by Walker and Dods on which u comment, it is stated that mental depression was a stinct feature of convalesence in some cases, and that patients looked well for at least a week after an attack average severity Full health was usually regained ite quickly once this phase had passed In my perience (which includes many more cases than the ries mentioned above) an aftermath of depression, th mental and physical occurred in almost all cases, d often lasted for months In none of my own cases d the depression go as far as suicide, but this has ppened in the experience of some of my colleagues he treatment generally adopted in Baghdad is full ses of tincture of opium and an aperient

POSTGRADUATE COURSE IN TUBERCULOSIS —The Joint berculosis Council has arranged to hold a postgraduate rse in tuberculosis and allied conditions at the Middlesex nty sanatorium, Harefield, from Sept 1 to 5 Special leave attend the course will be granted to members of the E M S rther information may be had from Dr Frederick Heaf, unty Hall, Westminster, S F 1

Obituary

DUNCAN FORBES

M B E M D, B SC (PUBL HLTH) EDIN D P H

DR Duncan Forbes, for thirty years Brighton's chief health officer, died on July 25 in University College Hospital, London, after an operation He was in his 68th year and leaves a widow, a son recently qualified in medicine, and three daughters of whom one was called to the bar in 1935 Forbes was an Aberdonian who qualified at Edinburgh in 1898, became Crichton scholar in pathology, and spent three years in intensive study of hygiene and acquiring higher degrees, before entering the public health service at Leith, passing on to Manchester and Cambridge, and in 1908 succeeding Sir Arthur Newsholme as medical officer of health for Brighton Between them they covered half a century and now, looking back on the intervening years, Newsholme writes of the integrity and originality which fitted Forbes to be the medical adviser of a community which in process of urbanisation remained one of the healthiest places of residence in the world Integrity shown in his indifference to popularity when he cleared the Carlton Hill slums and insisted on rehousing some of the dispossessed tenants on the site Originality when he discarded the outworn shibboleths of fumigation in favour of soft soap and elbow grease Forbes, the Scot, with native dourness and pawky humour, embraced the ideas and life of Southern England but lived a little apart from the ordinary social activities of the town, descending now and again into the arena to bring forward some quasi-Shavian solution of a current problem, as when a few weeks ago he propounded to the local health planning committee an embargo on meat and tobacco, the consumption of greenstuff raw, doubling the ration of potatoes, destruction of useless animals (especially dogs), and the emigration to Canada of people over 65 not engaged in essential work But behind the occasional pyrotechnic was a life of duty quietly and consistently lived, it was, for instance, told of Forbes that up to the day of his retirement in 1938 no case was discharged from the fever hospital without his personal inspection There will be many to miss the well-known figure, always in the same garb and never in an overcoat, striding over the Downs or to his office in Castle Square

LEONARD MORTIS WEBBER

M R C S, D P M

DR Webber, who died on July 25 following an operation, spent his life in the service of the Surrey county mental hospital at Netherne of which he had been superintendent since 1934 He was educated at Wellingborough and qualified from Charing Cross Hospital, where he won the governors' clinical gold medal, in 1909, becoming resident obstetrical officer there After a term at Lewisham Infirmary, as it was then called, he was appointed second assistant to Netherne, a year after it was opened, remaining there except for a break in the R A M C from Nov, 1915, to March, 1918 He was a sound psychiatrist, not quick to accustom himself to changes but giving full trial to established treatments and every encouragement to his staff to pursue them His main interest lay in the care of his patients and he would never spare himself in making them comfortable and happy He never missed their dances or entertainments He was greatly interested in occupational therapy and the departments grew through his efforts At first he was a little difficult to know and would hide his own shyness with a rather short manner, but his integrity, his genuine character and his real kindness were the foundation of solid friendships which grew as time went on He was a great reader, never at a loss to quote Thackeray or Dickens, he loved his garden and was very

Archer Handford Croydon

American Doctors for Britain

According to information recently received from the American Red Cross some 80 United States doctors who have applied to help in our medical services are at present being considered for acceptance, in addition to one who has already arrived and is at work in a civil hospital and four who are on their way to this country (Miss HORSBURGH replying to Sir HENRY MORRIS JONES)

Pasteurisation of Stale Milk

Mr W LEACH asked the President of the Board of Education whether he was aware of the unsatisfactory condition, supply and distribution of milk delivered to Southport schools, and of a report of the Southport health department which indicated that one sample of milk must have been stale before it was pasteurised, and whether any regulations exist which forbide the pasteurisation of stale milk —Mr R A BUTLER replied I am aware of the difficulties which have arisen in Southport about the supply of milk to schools, and my department have been in communication with the Ministry of Food who have taken the matter up actively I am informed by the Minister of Health that the conditions prescribed for pasteurised milk include a bacterial standard for the milk after, but not before, pasteurisation

Grants for Medical Research

Replying to a question Sir JOHN ANDERSON stated that the grant in aid of the Medical Research Council exclusive of a special capital grant of £70,000 for building in 1939–40 was £195,000 in each of the years 1938–41

Diphtheria Immunisation

Answering a question Mr E BROWN announced that statistics will be obtained from all local authorities in due course which will show, as from Jan 1, 1940, to what extent notification of diphtheria has occurred among children under 15 who have been immunised

Special Clothing for Disabled Men

Stump socks and certain other garments needed by disabled ex service men have recently been exempted from rationing Arrangements will be made in due course to meet any further needs of persons who for medical or other special reasons require more than the normal clothing ration, but I cannot say at present whether persons with artificial legs are likely to fall into this category (Captain C WATERHOUSE replying to Sir SMEDLEY CROOKE)

Hospitals and Army Road Casualties

Sir WILLIAM WAYLAND asked the Secretary of State for War what responsibility the War Office accepted for reimbursing a hospital for the cost of a patient injured by an Army vehicle, even though the cause of the accident might have been purely accidental or due to contributory negligence on the part of the injured person, or when the cause of the accident was in dispute —Mr D SANDYS, financial secretary to the War Office, replied When a person is afforded emergency treatment as the result of an accident arising out of the use of a War Department vehicle on duty on a road, claims are accepted against Army Funds for the cost of such treatment at the rates and in the circumstances specified in section 16 of the Road Traffic Act 1934, notwithstanding that that part of the act does not apply to the Crown Refund of other hospital expenses is considered in connexion with any claim to compensation arising out of the accident In general, the War Office accepts liability in respect of such expenses to the extent to which a private employer would be liable in similar circumstances

Home Guard Medical Officers

Captain H D R MARGESSON replying to a question said that instructions will be issued shortly authorising the appointment, where necessary, of medical officers to Home Guard companies, in addition to the officers at present authorised for battalions

Lack of Canteens in Scottish Mines

Replying to questions Mr T JOHNSTON said that the policy of the Government was to provide adequate nutrition for all classes of workers Any disparity in the provision of food canteens was receiving urgent attention At the coal pits in Scotland they were exceptionally badly off, they had only two canteens in active operation

ST JOHN OPHTHALMIC HOSPITAL, JERUSALEM —Dr Norman Manson has been appointed warden of the hospital in succession to Sir John Strathearn, who has resigned owing to ill health after holding the office for twenty two years

Letters to the Editor

"SIDEROCYTES" IN MAN?

SIR,—The presence of iron in the hæmoglobin m cannot be demonstrated histochemically It has been discovered that normal mouse and rat embryos newborn young have in their circulation a small centage of erythrocytes in which the presence of non-hæmoglobin iron can be demonstrated by of the prussian-blue reaction (Gruneberg, H July 26, 1941, p 114) These "iron cells" or cytes" are greatly increased in numbers in an anæmia in the mouse, which is associated with recessive gene for flexed-tail and belly-spot It be of interest to discover whether the presence of s cytes is an embryonic feature confined to rodents whether it also occurs in other mammals, particularly man I have recently examined blood-films (cord blood kindly supplied by Dr H H F Bains) of full-term baby girls It seems that a very few s cytes occur in these films, but on account of scarcity I do not regard the question as settled doubt It would thus be desirable to confirm this f in the blood of premature babies or, better still, in th blood of embryos obtained in therapeutic abortion As no such material is accessible to me at present, should be most grateful for suitable blood-films (thi fixed in absolute methyl alcohol, unstained, with dat about the approximate age and length of fœtus)

HANS GRÜNEBERG

Pathology Department, Mount Vernon Hospital,
Northwood, Middlesex

FOUR PHASES OF BIRTH

SIR,—Sir Joseph Barcroft's fascinating lecture is fu of points of first-rate importance for midwifery H revelation of the state of *semi-asphyxia* of the fœtus the last few weeks before birth emphasises the importan of paying particular attention to the maternal circulatio during these last weeks of pregnancy It is still too common to find women coming to term with seve anæmia and less commonly with circulatory disea The state of semi-asphyxia in which the child is bo adds interest to the undoubtedly successful results whi attended the use of the Sparklet resuscitator, althou this has somewhat fallen into disuse since more elabora methods of giving carbon dioxide have been used seems that the effect of the resuscitator was not due the carbon dioxide at all, but to the impingement on t baby's face of intermittent streams of gas which h been chilled by rapid expansion When warmer carb dioxide was used no such stimulating effect was obtain This confirms clinically Barcroft's finding that increa carbon dioxide in the blood in the fœtus does *not* stim late respiration but that the nasal area is extreme sensitive to stimulation which excites respiratory mo ment Your excellent abstract, when stressing t effect of asphyxia on inhibition (p 94), may mislead this point, for, unless my memory of the original lect at Aberdeen is at fault, Sir Joseph pointed *out* a demonstrated on the film that at term clamping t umbilical vessels had practically no power to init respiratory movements compared to the effect cutaneous stimulation

His further observations on the effect of cutane stimulation on respiration suggest, what I believe fact, that some of our very gentle methods of treat newborn babies fail in their object and I am sure t sometimes a sharp slap will start an asphyxiated ba breathing when the recommended gentle rubbing of skin and so on is quite ineffective The final sentence your abstract that "sensory impulses from the heighten the tendency towards respiration" is *of* very greatest clinical importance The remark that factors making for movement are "stimuli from the n mouth, skin or muscles reaching a brain of exalted sitivity" also seems to me important, because it sugg that what is required in the asphyxiated baby is n direct respiratory stimulant, if such exists, but someth which will exalt the sensitivity of the brain A w ago (*Lancet*, 1941, 1, 433) I reported the successful re of injecting 0 5 c cm of Cardiazol-Ephedrine into

At a meeting of the council held on July 31, with Sir red Webb Johnson, the president, in the chair, Prof exander Primrose of Toronto was appointed representative the college at the centenary celebrations of Queen's University, Kingston, Ontario, and Surgeon Rear Admiral G ordon Taylor as delegate at the annual clinical congress in oston of the American College of Surgeons

Diplomas of membership and diplomas in ophthalmic edicine and surgery and in medical radiology were granted o those named in the report of the Comitia of the Royal ollege of Physicians published above

Extra Meat for Cases of Nephrosis

The Food Rationing (Special Diets) Advisory Committee of the M R C have recommended that people suffering from nephrosis or the nephrotic type of glomerulonephritis should be granted three extra meat rations a week Doctors may therefore complete certificates on behalf of their patients suffering from these diseases for submission by the patient to the local food offices

Course for Surgical Specialists

Because of the need, both in the E M S and in the Services, for more surgeons with training and experience in the diagnosis and treatment of disabilities of the locomotor system, arrangements have been made for courses of instruction in the subject Each course will extend over six weeks and will provide practical experience and instruction for the whole of that period The surgeons attending the course will be divided into groups of not more than four, and each group will be attached to the wards and outpatient department of a senior surgeon experienced in this type of work They will have charge of cases, carry out treatment and receive practical demonstrations They will also attend the work and teaching at neighbouring hospitals, fracture departments and clinics The first course will begin on Sept 15, and will be given at Alder Hey Hospital, near Liverpool It will be conducted by Mr T P McMurray, Dr B L McFarland, Mr R Watson Jones, Mr F C Dwyer, Mr N E Thomas and Mr W R Mitchell In addition to Alder Hey Emergency Hospital, the Royal Infirmary, the David Lewis Northern Hospital and the Royal Southern Hospital, Liverpool, will be utilised This course is designed for surgical specialists in the E M S and Fighting Services, who should be of the status of junior honorary staff or senior registrars The number will be limited to 16, and applications should be sent as soon as possible to Dr F Murchie, Ministry of Health, Whitehall Suitable accommodation will be arranged through Mr McMurray in the neighbourhood of Alder Hey Hospital Before sending in their applications, medical officers in the E M S should obtain through the medical superintendent or medical officer in charge of their hospital the permission of the hospital officer or group officer, and those accepted will be granted special leave to attend the course Medical officers enrolled in classes 1, 2 and 4 will be continued on their existing contracts and will be refunded return travelling expenses from their present hospitals For those enrolled in class 3, in addition to travelling expenses, a subsistence allowance is authorised to meet the cost of their billeting

STERNAL BIOPSY IN DIAGNOSIS

In his Honyman-Gillespie lecture in Edinburgh last week Prof L S P Davidson said that the scene of interest in hæmatology had shifted from the peripheral blood to the bone-marrow That did not mean that the diagnosis of the majority of blood-diseases could not be made accurately from examination of the peripheral blood changes, but it did mean that biopsy of the bone-marrow had led to a much clearer understanding of the underlying mechanism which implemented the peripheral changes and had opened up a new field for studying the effects of therapeutic agents In addition it offered the only hope of making a correct diagnosis in certain macrocytic anæmias of widely differing ætiology which failed to respond to liver extract, and in conditions in which the presenting sign in the peripheral blood was leucopenia or thrombocytopenia In such diseases as cancer Hodgkin's disease, multiple myelomatosis and the lipoidoses the diagnosis might be established by finding the specific cellular elements in the bone-marrow while the peripheral blood might merely show some degree of hypochromic anæmia In such diseases the involvement of the bone-marrow tended to be local rather than diffuse and hence a negative finding was of no value Sternal biopsy might be of great service in excluding the presence of disease Although a well-marked leucocytosis occurred in the blood in many conditions it was only in lymphatic leukæmia that lymphocytic hyperplasia of the bone-marrow was found The bacteriologist and protozoologist were finding that valuable information could be obtained from the bone-marrow in such diseases as enteric fever, malaria and kala azar

Examination of the bone-marrow could be carried out during life either by trephining the tibia or sternum, or by sternal puncture Each method had advantages and disadvantages but the last had the widest application in view of its ease and quickness A study of the sternal bone-marrow before and at various stages after the injection of liver extract in cases of pernicious anæmia had shown that as early as 12 hours after injection a complete change occurred in the bone-marrow due to the maturation of the large number of megaloblasts In iron-deficiency anæmias, whether induced by hæmorrhage, toxæmia or nutritional deficiency, the bone-marrow showed an erythroblastic reaction, but the more severe the anæmia the more primitive the red cell precursors and in very severe cases the marrow contained primitive cells similar to the megaloblasts of pernicious anæmia In the white-cell diseases sternal biopsy had been of great service in the diagnosis of acute leukæmia and leucopenic leukæmia The peripheral blood might show a low white count and a doubtful differential count but the sternal marrow picture was diagnostic In both manifest and leucopenic lymphatic leukæmia Professor Davidson had always found the marrow crowded with lymphatic cells, in spite of the published statements that in the early stages a lymphocytic reaction in the marrow was absent In aplastic anæmia and in agranulocytosis the bone-marrow might either show a great reduction of the formative elements or else a hyperplastic state This indicated that in some cases there was a maturation arrest and showed an obvious need for further research into therapeutic agents which would restore normal maturation Thrombocytopenia might occur as a primary disease or as a secondary feature of recognised toxic and infective processes, or as part of a generalised blood disease such as aplastic anæmia or leukæmia In all forms of thrombocytopenia where the cause was not obvious sternal puncture should be carried out A study of the megakaryocytes, which he now firmly believed to be the precursors of the blood platelets, might show either a great reduction in their numbers—an aplasia—or a great increase In the latter cases the megakaryocytes were found to be of a very primitive type which might be called megakaryoblasts This finding suggested yet another form of maturation arrest and the discovery of a specific therapeutic agent would save many lives In multiple myelomatosis, cancer and Hodgkin's disease the marrow might be involved with metastatic deposits fond of his roses, and he had a great knowledge of birds His staff will miss him wholeheartedly

JAMES WILLIAM KEAY

M D EDIN, F R C P E, M R C P, D P H

Dr Keay medical superintendent of the Western General Hospital, Edinburgh, died suddenly on July 17 He had not been in good health for about a year but was improving and had been able to take part again in the administration of the hospital After graduating in medicine at Edinburgh University in 1903 he held house-appointments at Glasgow and Edinburgh infirmaries, later becoming clinical tutor in the gynæcological wards of the latter He took his D P H in 1909 and for a time he was school medical officer for Stirling, before entering general practice in Edinburgh He was elected F R C P E in 1910 At the outbreak of the last war he gave up practice and served in the R A M C with the rank of lieut-colonel On demobilisation he was appointed by the Edinburgh parish council to be superintendent of the Craiglockhart, Craigleith and Seafield Hospitals When the parochial functions were transferred to Edinburgh town council in 1930 he was appointed superintendent of the Edinburgh municipal general hospitals and played a large part in their reorganisation Since the outbreak of this war he had had much to do with the preparation of the hospitals for the reception of air-raid casualties Dr, Keay was approachable at all times, every one who knew his work appreciated his quiet manner and kindly disposition In the organisation of the municipal hospitals and their incorporation into the teaching facilities of Edinburgh University he often acted as a tactful intermediary between what were sometimes strongly conflicting interests

DR CHAVASSE

Sir Robert Kelly writes The tragic death of Bernard Chavasse at the early age of fifty-two removes from Liverpool one who could least be spared His zeal for work was unbounded, he took the liveliest interest in his hospital and was one of the most popular lecturers in the university I shall always remember a clinical meeting of the Medical Institution held at the Eye and Ear Infirmary, it was one of the most interesting I have ever attended and its success was largely due to Chavasse's enthusiasm He was an original thinker and in the last few years had spent much of his spare time on his book on "Squint" In this he treats binocular vision from the biological standpoint showing that true dual vision occurs in all vertebrates, even in those with widely separated eyes like the deer and the fish, and even in the swivel-eyed chameleon Chavasse took endless trouble with his many patients who will feel lost without him, his quiet demeanour gave them confidence His intellect and qualifications were of the highest order but he was always most modest about his achievements He had that rare combination of the trained mind of a research worker with infinitely delicate operative skill

---

Surgeon Commander Henry Hurst, R N, who was reported missing after the sinking of H M S *Hood* last May, was born in 1895 and qualified L R C S I in 1917 He joined the Navy at the beginning of the last year of war and remained in the service after peace was concluded, being promoted surgeon lieut-commander in 1924 He was twice congratulated by the medical director-general for operations performed at sea under difficult conditions, and in 1928 while serving at the R N Hospital, Hong-Kong, reported on his investigations into the treatment of amœbic dysentery The greater part of his leave was always spent in postgraduate study abroad and in 1932, after a period in the ear, nose and throat department of Haslar Hospital, he worked under Neumann in Vienna In 1937 he returned to practise this specialty at Haslar where he remained until he joined *Hood* in August of last year Hurst was an enthusiastic sportsman and played hockey, tennis, squash and water polo

THE work on penicillin briefly reported by Chain and others (1940) is here presented in greater detail, and its further development to the stage of human therapy is described

Growth of Penicillin-producing Mould

The mould will grow and produce penicillin on a variety of different media, but that used by Clutterbuck, Lovell and Raistrick (1932) is easy to prepare and gives as high a yield of penicillin as others containing peptone horse-muscle digests, &c This modified Czapek-Dox medium consists of $NaNO_3$ 3 g, KH_2PO_4 1 g, KCl 0 5 g, $MgSO_4$ $7H_2O$ 0 5 g, $FeSO_4$ $7H_2O$ 0 01 g, glucose 40 g, with water to 1 litre Oxford tap-water has proved as good as distilled water for this purpose Yeast-extract has usually been added to speed up the growth of the mould (details later)

The medium, sterilised by autoclaving, is sown with a spore suspension made by shaking up sterile water in a screw-capped bottle containing a slope on which the mould has grown and spored freely Twenty-four hours after sowing a very delicate fluffy gauze-like growth can be seen with difficulty on the bottom of the vessel (at 24° C) The growth becomes more voluminous during the next day and on the 3rd day, if the liquid layer is not more than 1 cm thick, this reaches the surface of the medium and throws up dry white mycelium, usually in isolated foci, particularly around the sides of the vessel Usually by the 4th or 5th day the whole surface of the medium is covered by dry mycelium, which about 24 hours after it appears begins to turn bluish green The colour is first seen at the centre of each focus of white mycelium, but it rapidly spreads outwards and by the 6th or 7th day the growth consists of a continuous, compact, often corrugated, dark greenish-blue felt whose upper surface cannot be wetted by water The under surface is of course freely wetted, and is brownish yellow and slimy If on the 1st or 2nd day the culture-vessel is disturbed or rocked the gauze-like growth tends to conglomerate into ropes and balls, and those parts of the surface of the medium which do not lie over these will only be covered several days later by secondary growths, for this reason once they have been sown the vessels should not be touched for some days Droplets, usually but not invariably yellow, may or may not appear on the surface of the mould, but the mould is never wetted by them As incubation is prolonged the colour of the mycelium becomes more faded and grey

The changes in the appearance of the mould are accompanied by changes in the pH of the medium, which starts between 6 and 7 and may fall as low as 3 by the 3rd day—usually as the dry mycelium is forming It then rises, reaching 5 as the greenish-blue colour appears At this stage a faint yellow colour can be seen in the medium and traces of penicillin can be detected The pH continues to rise and the titre of penicillin and the yellow colour both increase rapidly As the mycelium becomes more faded the pH rises more and more slowly, it seldom exceeds 8 8 Penicillin production is usually at its maximum at about pH 7, and may stay almost constant for some days or may fall again rapidly The pH is perhaps the most useful gauge of the state of the growth, apart from an assay for antibacterial activity The rate of development may be greater or less than that described, depending largely on the depth of the medium A systematic study of the factors influencing penicillin-production was begun, but it could not be completed owing to the very numerous and often interdependent variables, and to the fact that the assay-method then in use could only detect large differences of titre The following conclusions, however, could be drawn

1 Penicillin production seems to take place over a wide range of oxygen tension (The mould will not grow anaerobically)

2 The mould grows satisfactorily at 24° C At lower temperatures growth is delayed and as harvesting of the medium is carried out in the incubator higher temperatures have not been studied, 24° C being about the upper limit of comfort Fleming (1929) in his original description stated that the mould would not grow at 37° C and this has been confirmed

3 Crude attempts to change the pH of the medium or to maintain it at a constant value have not resulted in a noticeable increase in yield of penicillin, nor has the incorporation of ten times the normal amount of phosphate buffer

4 The medium should not have a depth greater than 1 5–2 cm If deeper than 2 cm diffusion is visibly inadequate, for two distinct layers can be seen in it, the upper being yellow, the lower colourless

5 When the medium is fit to be harvested it can be drawn off from under the mycelium and replaced with fresh medium in which more penicillin will form in about half the time required for the initial production The medium can be changed several times in this way, with one batch it was changed 14 times

6 The mould must be grown and the medium harvested and replaced under strictly sterile conditions since penicillin is destroyed by certain bacteria (Abraham and Chain 1940)

7 The addition of yeast extract (Gladstone and Fildes 1940) accelerates the growth of the mould but does not affect the yield of penicillin In large scale growth we have always used yeast extract, in starting a batch the medium is made up to contain 10% of it, but the medium used for replacement contains only 2½% The accelerating effect of the yeast is not impaired by prolonged autoclaving at a high temperature Marmite or malt extract have no effect on the rate of growth or on the yield of penicillin

8 The yield is not greatly affected either by doubling or by halving the strength of the medium

9 If the sodium nitrate is replaced by ammonium lactate the pH of the medium falls to below 3 and development almost ceases On adjusting the pH to about 6 5 development proceeds and the medium ultimately becomes very alkaline Very little penicillin is produced

10 The sodium nitrate can be wholly or partly replaced by peptone or by peptic and tryptic digests of muscle, and sucrose or maltose can be used in place of glucose, without materially altering the yield of penicillin

11 Occasionally a batch produces little or no penicillin Although this can generally be traced to bacterial contamination in some instances contamination could not be proved, and the suspicion arose that penicillin production might be a variable and easily disturbed function of the mould To test this, pure line cultures were made from single cells of two batches, one of which had given a yield of penicillin and the other none Five pure lines of the former and nine of the latter were inoculated in triplicate into bottles of medium and the penicillin titre was followed No difference could be detected between any of the lines, proving that the mould had not lost its power to form penicillin The possibility that the failure had been due to contamination by another mould was investigated, but no evidence of this could be found

Method of Assay

The serial dilution method used by Fleming (1929), which measures the lowest concentration of penicillin that will prevent growth of the test-organism in broth, is laborious and can only be applied to sterile material This at once reduces its usefulness for chemical investigations, for the material to be tested would have to be sterilised by filtration and it seems that under some conditions penicillin may be partially adsorbed on Seitz filter pads The method of estimation finally adopted is

* With personal grants from the Medical Research Council
† Philip Walker Student ‡ Nuffield Research Student

In the first the marrow might be widely and diffusely infiltrated and in a high proportion of cases an accurate diagnosis could be made by sternal puncture In cancer and Hodgkin's disease the deposits were usually more focal and the chance of obtaining specific cells much less, but Professor Davidson gave illustrations of cases in which sternal puncture had enabled the diagnosis to be made by the finding of carcinoma cells In such cases it was his practice not only to make smears of fresh marrow but also to allow the material obtained from the marrow cavity to clot and then to fix it and cut paraffin sections

EPIDEMIC JUVENILE DELINQUENCY

DISCUSSION at a council meeting in a county town has revealed an epidemic of wanton and wilful damage to property which provokes speculation A great part of the damage was done by children and the prevalence of similar offences in other places has been ascribed, perhaps correctly to the war-time disturbance of those ordinary restraints parental or other, that should normally keep juvenile behaviour in reasonable harmony with social demands In the discussion it was demanded that somebody should be 'made an example of" and complaints were made of slackness on the part of police and public in not taking action to that end The inertia complained of was blameworthy, but the assumption that making a punitive example would do more than satisfy moral indignation was a triumph of hope over experience There were possibilities in old-fashioned methods certainty of detection and swiftness of punishment at the hands of an incensed adult might in their results justify Bernard Shaw's advice never to strike a child except in anger but the law's deliberation is too slow to set up a conditioned reflex and in a juvenile community asocial enough to give prestige value to wilful damage any punishment the law can inflict is likely only to increase that prestige For better or worse we have now reached a state of things in which severity of punishment is not relied upon for the solution of a miniature social problem like this But the study of individual cases of delinquency has taught us a great deal about its causes in general and about the play of forces that may result in group delinquency, child-guidance clinics exist for the investigation and handling of the difficult or delinquent individual, and perhaps the day is not far off when social workers will be called upon to investigate and report on troublesome geographical groups

WHERE ARE THE SANE, JUST AND PEACEFUL?

THE League of Nations was a good idea but it failed in practice because there was no genuine international public opinion to support it Prof G W Keeton, director of the New Commonwealth Institute, founded in 1934 to "discover and disseminate knowledge of the true foundations of a sane, just and peaceful world order," believes that the achievement of the world commonwealth is an educational process, and this is the basis of his "Case for an International University" (Watts & Co 6*d*) "Any competent lawyer," he writes, "can draft a constitution for the world in a few hours The whole problem is how to make the behaviour of human beings in the international sphere conform to the standards which have been accepted within an individual State" The trouble is that people still think nationally instead of internationally, whereas cooperatively the human race could be, even materially, much better off than it is today An international university would teach the lesson of history—that wars will survive so long as national interests override the common welfare So far so good but the professor says, first, that before this war is over the British Commonwealth, the United States and Latin America will be so firmly knit together that no-one will be able to separate them, secondly that there is something unpleasant in the German national character which must be eradicated, and thirdly, that Russia has always been substantially outside the orbit of Western civilization, which is attached to values that differ widely from those which unite the Russian masses In 1941 these statements seem like an echo of 1917 If the world is to be divided into the three camps he indicates, will there really be no more war for Professor Keeton's international undergraduates?

PAYING CASUALTIES

THE Government provides free medical and treatment for civilian and service casualties but casualty chooses to make his own arrangement treatment as a private patient he must pay for his treatment Accompanying the Minister of H circular (No 2438) explaining this principle there declaration which the patient (or a relative) will be to sign when deciding to seek private treatment T casualty formally relinquishes his claim for free tre ment and agrees to pay for the treatment which he arranging for himself These paying patients fall out the Emergency Hospital Scheme—and the beds th occupy should not be included in the hospital's retur to the Minister Officers however are not accommodated in the general casualty wards and civilian casualties may also for medical reasons sometimes need separate rooms To provide for these special casualties a hospital may have to set aside some of its paying beds and the e bed will then come under the E H S , and their occupants may not be charged any fees When these beds are no being used for casualties they may be used as priv beds for the civilian sick, as distinct from casualties just as beds in the ordinary wards are at the disposal of the hospital in case of need Whole-time (class I) E M S officers are not entitled to fees from private patients but class II and class III officers may engage in private practice provided the Minister has first call on their services

---

INSTRUMENT STERILISING FLUID —Messrs Boots have carried out bacteriological and metallurgical tests with their product Kramsol, a solution containing formaldehyde, amyl-meta-cresol and borax intended for sterilising surgical instruments Cultures of *Staphylococcus aureus* and *Streptococcus fæcalis* mixed with blood were killed by a 1 in 3 solution in 5 minutes Various instruments immersed in a suspension of spore-bearers, staphylococci and streptococci were rendered sterile by immersion in undiluted kramsol for 4 hours and a suspension of spore bearers was killed in 6–24 hours Steel and plated instruments lost no weight by corrosion during immersion for some weeks except where the plating was faulty o brass and steel came in contact, rubber and bristle were undamaged

PHENYTOIN SODIUM (B D H)—Under this name British Drug Houses have issued their preparation of sodium diphenylhydantoinate for the treatment of epilepsy The drug is in tablet form, each tablet containing 0 1 gramme

Messrs ALLEN & HANBURY have lately added Euval erol D to their Euvalerol elixirs It contains an extr of valerian prepared from the fresh root with chlor hydrate gr 20 and strontium bromide gr 10 in each fluid ounce, and can be prescribed as a sedative o hypnotic It is available in 4-oz and 8-oz bottles

Births, Marriages and Deaths

BIRTHS

FIFE —On May 3 at Roorkee, U P India, the wife of Capt J Gordon Fife, I M S —a daughter

GUERRIER —On July 28 at Horton Kirby, Kent, Dr Shel Guerrier the wife of Dr Hugh Guerrier—a son

HICK —On Aug 1 at Windsor, the wife of Captain Alan Hi R A M C —a son

MACGREGOR —On July 30 in Edinburgh the wife of Surge Commander William M Macgregor, R N V R —a daughter

STEVEN —On July 28 at Bath to Dr Muriel Steven, the wife Major G D Steven, R A M C —a son

THOMPSON —On July 28 at Chippenham, the wife of Major Geoffr Thompson, R A M C —a daughter

MARRIAGES

BALDRY—KERRIDGE —On July 29 at Farnham Charles Vic Nelson Baldry, M R C S to Dorothy V Kerridge

ISAAC—SHARP —On July 30 at Battersea Paul William Isaac, M surgeon lieutenant R N V R to Enid Estella Sharp

REES—TEESDALE —On July 26, at Epsom, John Emlyn Re M R C S , to Lyn Teesdale

DEATHS

CLARK —On July 20, Alfred Joseph Clark, M C M D Cam F R C P , F R S

HAYDON —On Aug 1, at Bideford, Frank Haydon, L R C aged 79

WILLIAMS —On July 28 at Farnham Surrey Charles Edw Williams M B Camb , lieut colonel I M S retd aged 7 e fluid is drawn out by tube G   Suction and pressure are ntrolled by the single trigger H of the "pistol"   A fresh ibe G is used for every batch of four vessels and F is changed ter every two batches   Both tubes are sterilised wrapped in aper and only one end of the tube is unwrapped when being fitted into the pistol, the tubes are unsheathed from the remaining paper wrappings immediately before use   From the pistol the harvested medium passes to the inverted bottle K, in which it is filtered through a silk bag   The filtered liquid than passes to the collecting bottle L which is changed after every batch of four vessels   When not in use the pistol is hung on the pin M   For refilling the vessels are tilted at about 45°   A fitting on each wooden slab enables the vessel to be wedged in this position (as shown by vessel N in fig 3), so that both hands are free to manipulate plug and bottle of medium

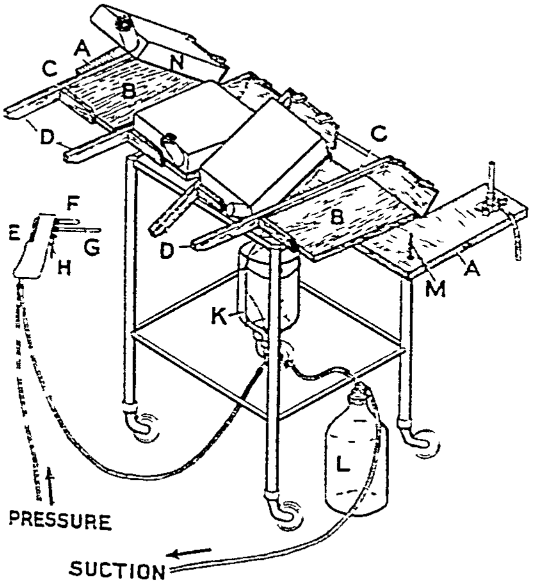

FIG 3—Changing trolley

EXTRACTION FROM CULTURE MEDIUM

Principle—Penicillin can be extracted by ether, amyl acetate and certain other organic solvents from an aqueous solution whose pH has been adjusted to 2   From the organic solvent the penicillin may be re-extracted by shaking with phosphate-buffer or with water the pH of which is kept at 6–7   Penicillin is quickly destroyed at pH 2 at room temperature, so the first extraction must be carried out rapidly or at a low temperature   Once it has been extracted into solvent the penicillin is stable for some days

Laboratory large-scale extraction—It was planned to produce a weekly output of about 500 litres of the crude medium containing penicillin, the working up of which by hand would obviously have been out of the question   A continuous, countercurrent extraction apparatus was devised, an adequate description of which cannot be included in this paper   The crude penicillin, having been filtered and acidified, is passed through special jets which break it up into droplets of uniform size   These are allowed to fall through a column of amyl acetate, to which the penicillin is given up   The crude solution is acidified immediately before entering the jets, so that the aqueous solution is at a pH at which penicillin is unstable for only a few seconds before it has been extracted   As the crude solution is passed through a cooling coil surrounded by circulating tap-water probably very little destruction of penicillin takes place   Phosphoric acid is used for the acidification as the pK of the first stage of dissociation is approximately 2, it will therefore act as its own buffer and inaccurate correlation of the rates of flow of the acid and of the crude solution will not cause big fluctuations in the final pH   Fresh solvent is continuously fed in to the bottom of the column, from the top of which an equal amount of penicillin-rich solvent is collected for further working up   This solvent has 1/10–1/5 of the volume of the crude solution from which the penicillin has been extracted, and many impurities, notably those forming emulsions have been eliminated

The preparation used in the mouse-experiments previously reported (Chain et al 1940) was purified only to the stage of recovering the sodium salt from a first ether extract (ether was at that time used instead of amyl acetate)   Though strongly active this product probably had less than 1/10 of the activity of our present "therapeutic penicillin"   A batch intended for injection into man was first tested on mice   A mouse was little affected by the intravenous injection of 10 mg in 0 3 c cm of water but became very ill after receiving 20 mg, though it recovered in about 1½ hours   When given intravenously to an afebrile human subject 100 mg of the same material caused a shivering attack with a rise of temperature in about an hour   Trial on other subjects gave the same result and left no doubt that a pyrogenic substance was present in the preparation   The pyrogen can be assayed by the method used by Lees and Levvy (1940) in which five rabbits of uniform weight (a little over 2 kg) are kept at a constant temperature (67° F)   On the day of the test they are deprived of food and the rectal temperature is taken hourly   Twenty milligrammes of the substance used in the mouse experiments dissolved in 1 c cm of distilled water, injected intravenously, gave a rise of about 2° F in each rabbit, but "middle fraction" from the adsorption column (see below) had no pyrogenic effect   The further purification here described secures a pyrogen-free product suitable for intravenous use

Further purification—Batches of 3 litres each of the penicillin-containing solvent as delivered from the extraction-apparatus are extracted with five successive amounts of 300 ml each of water, using baryta to adjust the pH to 6 5–7   The five watery solutions have already been used for former extractions and are used in order of decreasing concentration of penicillin   The first extract, which is the strongest, is set aside for further working up, but a sixth extract is made with fresh water so that the number of watery solutions remains the same   The amyl acetate which may still contain a small amount of penicillin, is recirculated in the extraction apparatus   In the course of time pigment accumulates in the solvent and is periodically removed by extraction with 1% sodium hydroxide followed by thorough washing

The strongest aqueous extract is partially decolorised by shaking with about 8% of animal charcoal and filtering   The charcoal residue is washed twice, the washings being put through the extraction apparatus or used in other ways   The partially decolorised solution is cooled acidified and extracted into successive amounts of ether   the strongest of the ether extracts is then passed through an adsorption column of Brockmann alumina   The spent ether contains solid matter but no penicillin, which remains behind in the column   Though the chromatograms vary, four main zones can be seen, their boundaries overlapping to some extent   These are, starting from the top

1 A dark brownish orange layer whose depth is inversely proportional to the amount of charcoal used for the decolorisation and which may be absent altogether   This layer contains some penicillin

2 A light yellow layer containing most of the penicillin but none of the pyrogen

3 An orange layer which contains some penicillin and some or all of the pyrogen

4 A brownish or reddish violet layer which contains practically no penicillin   The violet pigment disappears on exposure to light

The column is washed by passing successive small amounts of ether through it and is then divided into the four fractions, of which the fourth is discarded   The others are eluted with successive amounts of M/15 phosphate buffer (pH 7 2), from the strongest of which the penicillin is again extracted into ether, while the more dilute solutions are used for the elutions of the next batch   Finally the penicillin is extracted back into water using sodium hydroxide to adjust the pH   (As the solution is not buffered the greatest care must be taken in adding the alkali, for penicillin is rapidly destroyed in alkaline solution)

The "non-pyrogenic" or "therapeutic" fraction, which contains perhaps 80% of the penicillin put through the column, is extracted into pyrogen-free water, all glassware having been rinsed with the latter   It is a deep reddish-orange fluid, yellow in dilute solution with a faint but characteristic smell and a bitter taste as follows Ordinary nutrient agar plates are seeded with the test organism—*Staphylococcus aureus* has been used in this work—by allowing a broth culture of the organism to flow over the surface of the agar and draining off the excess broth The plates are then dried for an hour in the incubator at 37° C in a special rack which supports the lid of the Petri dish half an inch above the lower part When dry the seeded plates are removed from the incubator and can be kept in the refrigerator for one or two days Cylinders made from short lengths of glass tubing, the dimensions of which will be seen from the inset of fig 1, are placed on the agar The lower edge of the cylinder is carefully ground level and has an internal bevel so that the thin edge tends to sink into the agar and make a water- and bacteria-tight seal Vitreous porcelain cylinders of the same size and shape, coloured at the non-bevelled end to facilitate their orientation, have also proved satisfactory The cylinders are filled with the fluid to be tested, and the plates, resting on a block of wood, are incubated for 12–16 hours at 37° C (If placed directly on the warm incubator shelves moisture may condense on the lids of the Petri dishes and drop on the agar, thus obscuring the results) By the end of incubation most of the fluid in the cylinders has disappeared and each cylinder is surrounded by a circular zone where no bacterial growth has occurred The diameter of the zone depends on the concentration of the penicillin, the type of relation being shown in fig 1

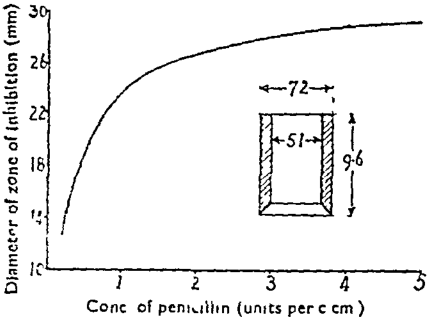

FIG 1—Relation between assay value and concentration of penicillin in solution being tested *Inset*—Median vertical section through assay cylinder, dimensions in mm

The possibilities and limitations of this method of assay have not yet been fully worked out but the following points may be noted

1 The diameter in mm of the zone of inhibition (which we have called the "assay value") is only slightly smaller (1–2 mm) when the cylinder is half filled than when it is fully filled

2 The assay value is unaffected by the pH of the fluid being tested, provided it is not strongly buffered and lies within the range pH 5–8 5

3 No inhibition is produced by a saturated aqueous solution of ether or by water containing free droplets of chloroform

4 Diffusion of penicillin seems to be practically complete in 2–3 hours, and assay values after 14 hours of incubation are only very slightly smaller (0 5–1 mm) than after a further 8 hours at 37° C

5 Provided the plate is not jarred the fluid cannot escape from the cylinders, and even if the fluid is not sterile the contaminating bacteria are confined to the inside of the cylinder

6 The assay value is not affected by the thickness of the agar provided it is between the limits of 3 to 5 mm

7 The assay value varies slightly with different batches of plates and with the density of bacterial population at the beginning of incubation For this reason uneven seeding of the plates must be avoided

8 Sometimes the clear zone of inhibition is surrounded by a halo of partial inhibition, which varies from a faint ghost to almost complete inhibition So far no explanation for, or means of controlling, this phenomenon has been discovered

9 When the antibacterial activity of blood is to be assayed plasma or serum must be used, since red cells tend to form a layer immediately on top of the agar which seriously impedes the diffusion of penicillin and leads to low values

High accuracy cannot be claimed for this method of assay, but if it is done in triplicate (preferably on three different plates), and if the unknown solution is diluted so as to give an assay value of not more than 25 mm (before the curve has flattened out), the error is probably not greater than ± 25% and may be considerably less We have no evidence that under suitable conditions this method is inferior in accuracy to the serial dilution method and it is certainly many times quicker In addition, less than 0 25 ml of fluid is required for each test

Unit of antibacterial activity —When day-to day comparisons have to be made rather large errors may be introduced for the reasons mentioned in note 7 above, unless a standard is set up on each plate to which all the assay values may be related We have been using as such a standard a partially purified solution of purely arbitrary strength It is made up in dilute phosphate buffer, is saturated with ether and is kept in the ice chest It gives an average assay value of 24 mm and as far as can be seen its activity has not altered during the three months in which it has been in use We have adopted as the arbitrary unit (until penicillin is obtained chemically pure) *that amount of penicillin which when dissolved in 1 c cm of water gives the same inhibition as this standard* The material used in the human therapeutic tests usually *contained 40–50 of these units per mg*

Large-scale Production of Penicillin

Culture vessels and sowing —After many types of containers had been tried a satisfactory ceramic vessel was eventually designed,[1] the shape and dimensions of which can be seen in fig 2 The vessels are glazed only on the inside, this both reduces the cost and renders them easier to handle and less liable to slide when stacked one on top of the other The inset of fig 2 shows a convenient way in which they can be stacked for autoclaving, sowing and so on, each plug is well separated from the other but no bench space is lost, and should the medium boil in the autoclave the plugs are unlikely to be wetted One litre of medium fills the vessels to a depth of about 1 7 cm When a batch of vessels is first set up the medium (containing 10% of yeast-extract) is sterilised in the vessels, which are then inoculated with a few drops of a spore-suspension[2] and incubated at 24° C Apart from an occasional test the vessels are not touched until the medium is ready to be harvested

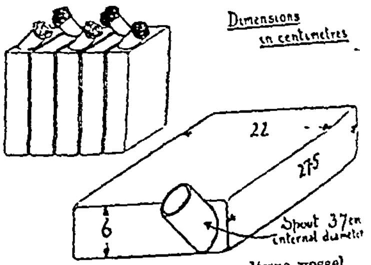

FIG 2—Earthenware culture vessel *Above* —Vessels stacked for autoclaving

Arrangements for withdrawing and replacing medium —The penicillin-containing fluid is withdrawn from the vessels and replaced with fresh culture-medium To carry out these two processes without introducing contamination is far from easy and needs thorough bacteriological precautions In order to hasten the production of penicillin we attempted to reduce these precautions to a minimum, and at first obtained satisfactory results, but lately contamination has become so frequent that substantial modifications have had to be introduced, some of which are still on trial and therefore cannot usefully be described

The withdrawal of culture-medium is done by suction, the medium being replaced with sterile air In the original method the refilling was done by simple pouring, but safer methods (not yet finally determined) have now been introduced, and precautions at all stages are being tightened up

The operations can conveniently be carried out on the "changing trolley" (fig 3), made by replacing the top of a small all metal table by a wooden plank A, to which are hinged the four wooden slabs B on which the vessels are placed The raised rim C is prolonged into a handle D, by which the slab (and the vessel on it) can be tilted forward The slab is not hinged square with the edge of A, but at a slight angle to it, so that on depressing the handle D the fluid in the vessel drains not merely to the front edge but to the corner nearest the spout The medium is drawn off by suction with the help of a special pistol shaped holder E, carrying two detachable sterilised tubes F and G F is plugged with cotton-wool before sterilising, and through it is blown into the vessel a current of (sterile) air at a somewhat faster rate than matise themselves to inhibitory concentrations of cillin, and if so whether they do so by producing the cillin-destroying enzyme penicillinase which has been onstrated in certain saprophytes and commensals aham and Chain 1940), a strain of *Staph aureus* was vated for some months in broth in the presence of easing quantities of comparatively crude penicillin n after a few daily subcultures there was evidence of eased resistance, the coccus showing growth in at t twice the previously inhibitory concentration In out nine weeks, with subcultivation every few days, approximately 30-fold adaptation was reached, and er a further 7 weeks the microbe was able to multiply in oncentration of penicillin a thousand times greater than at which inhibited the parent strain in a parallel test—ile the parent was almost completely inhibited by 1 in million, the adapted strain grew quite well in 1 in 1000

---

[1] Made for us by J Macintyre and Co, who also made the porcelain assay cylinders

[2] The strains of penicillium used in this work have been obtained from Prof Alexander Fleming of St Mary's Hospital London

Contrary to expectation the main general effect of laptation to penicillin was a reduction both in the elocity of growth in ordinary media and of enzyme ctivities The adapted strain was repeatedly tested in omparison with the parent strain on a range of fermentble substances, and it was found that although after 0–14 days of incubation both strains showed the same eactions (acid in glucose, lactose, maltose, mannitol and accharose, no change in dulcitol , liquefaction of gelatin, acid and coagulation in milk) the adapted strain showed a considerable lag, taking 2 days instead of 1 to acidify lactose, 4 days instead of 1 for mannitol, and 11 days instead of 1 to coagulate milk. A reduction of growth-velocity in nutrient broth and agar was also seen and hæmolysis on blood-agar plates was much delayed Both strains however gave a good coagulase reaction

Both about the middle (9 weeks) and at the end of the experiment just described attempts were made to discover in the adapted strain a penicillin-destroying enzyme not present in the parent coccus The adapted staphylococcus was grown on nutrient agar in two batches of 20 rolled Winchester bottles, in order to obtain a sufficient amount of bacterial bodies to be used in the bacterial crushing mill of Booth and Green (1938) The rather poor growth was washed off after 3 days, centrifuged, washed with water, centrifuged again and made up with water to a pasty consistency It was then ground in the crushing mill for 3 hours After the crushing, which was very satisfactory, the extract was centrifuged at 7000 revs for 20 minutes 1 c cm of the extract was then incubated with 1 mg of penicillin for 5 hours at 37° C There was no sign of loss of penicillin-activity after this period There is therefore no evidence that the adaptation of the staphylococcus to penicillin depends on the production of a penicillin-destroying enzyme by the organism

In an earlier experiment, aimed at discovering whether the resistance of insusceptible bacteria is due to their power of destroying penicillin, *Bact coli* was cultivated in broth containing the strongest non-inhibitory concentration of penicillin for this organism (1/400) Incubation overnight produced a rich growth of the bacterium The culture was then Seitz-filtered and the filtrate was tested in serial dilutions on *Staph aureus* Complete inhibition occurred up to 1/500,000 which was the full titre for the batch of penicillin used It could therefore be concluded that the growth of *Bact coli* had not caused any destruction of the penicillin

EFFECTS OF SERUM, BLOOD, PUS, TISSUE AUTOLYSATES AND PEPTONES

In view of the inhibitory effect known to be exerted by products of tissue autolysis on the action of the sulphonamides, it was natural to look for a similar effect on penicillin None, however, was found

Serum —To exclude any such action on the part of blood-serum, penicillin was diluted with human serum and tested on the staphylococcus by a modification of the assay method described above

The modified method consists of making shake cultures of the microbe, in this case *Staph aureus*, in narrow glucose agar tubes, solidifying and then running 0 6 c cm of the penicillin or other solution on the top After 24 hours' incubation at 37° C a zone of clear medium is seen below the fluid and above the zone of growth A small inoculum of cocci gave the best results—e g one standard drop of a 24-hours broth culture diluted 1/100 added to 5 c cm of melted glucose agar

When penicillin diluted 1/10 000 with serum was thus tested in comparison with the same dilution in distilled water both in duplicate, the depth of the zones of inhibition measured in millimetres

In serum	(1) 23–24	(2) 22
In water	(1) 22	(2) 23–24

Serum, therefore, in no way interferes with the action and diffusibility of the active substance

Whole blood —One or two experiments were done in slide-cells to test the action of whole blood and of these it is enough to say that in one such experiment a penicillin dilution of 1 in 2 million in human blood inhibited a dose of *Strep pyogenes* which, when plated, produced about 50,000 colonies per c cm of inoculated blood Other experiments agreed in demonstrating that there was no antagonistic effect

Pus —With regard to pus, the following experiment failed to show any antagonistic action

Some very thick pus from a *Staph aureus* abscess was incubated for 3 days at 37° C to "thin" it, after centrifugalisation the supernatant fluid was diluted 1 in 2 with nutrient broth and filtered through a Seitz filter To 2 25 c cm of this 50% pus-broth 0 25 c cm of a solution of 0 2 mg of (impure) penicillin per c cm was added, making a penicillin dilution of 1 50,000 As a control 2 5 c cm of the pus broth without penicillin was taken Both these were inoculated with one standard drop (0 04 c cm) of a 1 1000 dilution of a 24 hour broth culture of *Staph aureus* The number of cocci in the inoculum was probably of the order of 40,000 After 24 hours' incubation at 37° C the control tube showed a rich growth of staphylococcus and the penicillin tube showed none Platings from this tube and cultivation of 20, 5 and 1 drops in 5 c cm broth tubes showed no growth, indicating that at least most of the cocci had been killed, since the amount of penicillin carried over with 1 drop (1 in over 6 million) was insufficient to inhibit growth

A similar experiment was done with a sample of urine loaded with pus due to infection with *Bact coli* and *Strep fæcalis* In this case several dilutions of penicillin were made in the filtered 50% pus-broth—1/50,000, 1/150 000, 1/450,000 and 1/1 350,000 The inoculum of *Staph aureus* was the same as in the previous experiment After due incubation the two stronger concentrations of penicillin showed complete inhibition of staphylococcal growth, while in the two weaker ones as in the control of 50% pus-broth alone, full growth occurred Since the full antistaphylococcal titre of the sample of penicillin used was only about 1/250,000 the experiment gives no evidence of any antagonism by the pus

Tissue autolysates —The possibly antagonistic effect of tissue autolysates was tested as follows

A liver taken aseptically from a rat was minced in the homogeniser of Potter and Elvehjem (1936) and allowed to autolyse in the homogeniser tube for 4 weeks at 37° C. There was no gas evolution during the incubation and no putrefactive smell at the end of the experiment The liver suspension had partly liquified and when it was centrifuged about 2 c cm of a clear, dark yellow solution were obtained This fluid (0 9 c cm) was incubated at 37° C for 16 hours with a penicillin solution in water (0 1 c cm) containing 1 mg of the crude material A control solution of 1 mg of penicillin in 1 c cm of water was incubated for the same period When after incubation the solutions were assayed, it was found that the liver autolysate had not destroyed the bacteriostatic power of the penicillin.

Peptones are equally devoid of antagonistic action ; in fact in the usual assay method agar containing peptone is used as the culture medium for the staphylococcus

CHARACTERISTICS OF ANTIBACTERIAL ACTION

The bacteriostatic power of penicillin against streptococci and staphylococci is as great as, or greater than, that of the most powerful antiseptics known, such as the heavy metal compounds, the acridine derivatives &c. Yet penicillin is no antiseptic ; it exerts no direct immediate bactericidal action. This was borne out by two observations First, the oxygen uptake of staphylococcal suspensions was not inhibited to any measurable degree by the addition of penicillin to a final concentration of 1/1000 over a period of 3 hours Secondly, after incubation at 37° C for 24 hours a staphylococcal suspension in broth containing 1/1000 penicillin grew

Yields and losses —The crude medium, as harvested, usually contains between 1 and 2 units per c cm and the dried purified therapeutic material has an activity of 40–50 units per mg A hundred litres of the medium, containing, say 150 000 units, gives a yield of about 1 g of therapeutic material containing, say, 45,000 units, so that about a third of the penicillin present is actually extracted in a form suitable for intravenous injection There are many stages in the preparation at which the loss may occur and as far as possible these have been checked individually, but owing to overlapping of different batches during the working up (e g , in serial extraction) and insufficient accuracy in the assay method, it has been difficult to analyse the losses accurately. No big loss, however, occurs at any one stage

Storage and dispensing —The strong aqueous extract saturated with ether is quite stable It is stored either as it is in the refrigerator, or is dried by the lyophilic method and kept in a desiccator, as the voluminous yellow powder is hygroscopic A solution of the sodium salt of penicillin in water kept in the ice-chest for 3 months did not lose any activity The barium salt kept dry at room temperature in the desiccator retained its activity for at least 8 months In dispensing the material for intravenous injection it is assumed that the ether-containing solution is sterile, but most of the ether must be removed by suction before use The ether-free solution is stored in the ice-chest in measured doses

BACTERIOSTATIC ACTION OF PENICILLIN

Using purified penicillin more than a thousand times stronger than the crude material employed by Fleming in 1929, we have been able to obtain more precise information about the bacterial species he examined and also about a number of other important pathogenic organisms

Method —To 4 5 c cm quantities of fluid culture medium 0 5 c cm of graded dilutions of a strong, filtered penicillin solution were added Each tube of a series was then inoculated with a standard drop (0 04 c cm) of a 24 hours fluid culture of the microbe under investigation In the case of the robust organisms, such as *Staphylococcus* or *Bacterium,* the culture was usually diluted 1 in 100 or 1 in 1000 before use All tests were done in duplicate Complete inhibition was shown by the absence of turbidity after 24 hours at 37° C , the control culture showing good growth , partial inhibition was recorded when the growth was clearly less than that of the control

Results —In table I the bacterial species are arranged as far as possible in their order of sensitivity, but both the order and the actual figures must be taken with reserv As the work progressed the penicillin was becoming purer and stronger, so that some of the figures obtained in the early stages may well be too low Moreover, there has sometimes seemed to be some loss in potency of penicillin solutions when sterilised by Seitz filtration, a point that needs further investigation Finally, only a few species have been tested in more than one medium and with a minimal inoculum, both of which factors influence the observed titre

Certain species, such as pneumococci and *Strep viridans*, cannot be put in a single place in the order of sensitiveness because they show great strain differences and it will be noted that in the pneumococci these cut across the type distinctions Maclean, Rogers and Fleming (1939) have recorded a similar variability in sensitiveness to sulphapyridine of individual strains of the pneumococcal types It seems likely that an experimental comparison of the effects of the two inhibitory agents on a wide range of pneumococci would throw light on their modes of action

The testing of *Myc tuberculosis* was not easy Owing to the imperfect stability of penicillin at 37° C and the slow growth of the microbe it was inadmissible merely to incorporate the inhibitor with the medium at the outset The microbe was therefore cultivated in glycerol-broth, and penicillin solution was added every 2 days in such a way as to maintain at least the stated concentration for 14 days The microbe grew well in all dilutions A similar experiment had already been done by Dr R L Vollum, with similar results

It should be noted that complete, or even partial inhibition of macroscopic growth after 24 hours of incubation is not the most delicate criterion of antibacterial action. In somewhat higher dilutions the growth is retarded, and, as has already been recorded (Gardner 1940), a microscopical effect on the bacteria, indicative of defective fission, may often be seen far beyond the macroscopically inhibitory dilution We cannot say whether the virulence of the bacteria is thereby reduced , but if it is the effect may be of therapeutic importance For example, in one experiment with *S typhi* (*Bact typhosum*), whereas the last visible, partial inhibition was at 1/10,000, an elongation of the cells was microscopically detectable up to 1/60,000, a concentration which may be a therapeutic possibility

Adaptation of Staph aureus to penicillin —In order to find an answer to the questions whether bacteria will

TABLE I—DILUTIONS OF PENICILLIN AT WHICH VARIOUS INHIBITORY EFFECTS HAVE BEEN OBSERVED

Bacterial species	No of strains	Dilutions at which inhibitory effects were observed			Notes
		Complete	Partial	None	
N gonorrhϾ	6	2,000,000	>2,000,000	>2,000,000	—
N meningitidis	1	1,000,000	2,000,000	4,000,000	—
Staph aureus	4	1,000,000	2,000,000	4,000,000	—
Strep pyogenes	3	1,000,000	2,000,000	4,000,000	—
B anthracis	1	1,000,000	2,000,000	4,000,000	—
A bovis (hominis)	1	1,000,000	2,000,000	4,000,000	Deep glucose agar shake cultures
Cl tetani †	1	1,000,000			Limit not observed
Cl welchii	1	1,500,000			
Cl septique	1	300,000	1,500,000	7,500,000	Fivefold dilutions used

* Another strain was only inhibited up to 32 000 † Grown in Lemco broth In beef broth complete inhibition only reached 100,000
‡ In *Pneumococcus, Strep viridans* and anaerobic streptococci different strains appear at different levels in the table

tissue and the embryonic age The method determines erial dilutions the drug concentration *just sufficient* ippress all outgrowth of fibroblasts from fragments ie ventricle of the 10 day old chick embryo when bated for 24 hours at 37° C The drug is dissolved in an l mixture of fowl plasma and Ringer and the dilutions ared from it form a series each member of which is nine- hs of the strength of its predecessor At each level of the e five or ten explants are grown in separate chambers each aining 0 1 ml of the medium Inspection of the culture es after 24 hours makes it possible to determine the thres- l concentration of the drug for total growth inhibition ler the conditions described

Results—The threshold concentration for penicillin der the conditions described is 1/800 Growth at half s concentration (1/1600) is feeble and is arrested after e 24th hour of incubation The cells are small and cuolated and undergo retrogressive changes leading to igmentation and death if contact with the drug is olonged. The lowest concentration so far examined by is method, 1/6000, is still detectably toxic to fibroblasts

If the culture series used in the experiment described bove is maintained for 48 hours and each explant is then ashed for an hour in Ringer and re-cultivated into a ormal medium it is possible to give an estimate of the inimum lethal concentration of the drug—i.e , the oncentration which the standard explants are just able to withstand for 48 hours without undergoing changes which are irreversible by further cultivation For penicillin this concentration is well below 1/1200 and rather higher than 1/1600 Explants re-cultivated after 48 hours' subjection to 1/1600 penicillin are in fact capable of resuming normal growth and activity after 3 or 4 additional passages in a normal medium

It is interesting to contrast these two figures for penicillin—1/800 and 1/1600 for threshold point and minimum lethal concentration respectively—with those for proflavine under similar conditions The corresponding values are 1/120,000 and 1/250,000

The action of penicillin on epithelial tissues (10-day chick embryo intestine and lung, late rat-embryo kidney) can be investigated by growing small fragments on the surfaces of a series of coagula containing falling concentrations of the drug Epithelial tissues proliferate freely for 48 hours on the surface of coagula containing 1/2000 penicillin. Degenerate growth with maceration of epithelial sheets can be obtained in concentrations as high as 1/1000 Penicillin has no power of differential inhibition for fibroblasts and epithelia , from a specified source fibroblasts and epithelia either grow together under the influence of the drug, or neither grow

TABLE II—EFFECTS OF PENICILLIN ON HEN S BLOOD MACROPHAGES IN VITRO DURING A SINGLE GROWTH CYCLE

Final conc. of penicillin	Latent period	Mitotic activity	Cell morphology	Remarks
1/10,000 1/2000	Slightly prolonged	Strong	Unchanged	No after effects
1/500	Prolonged	Reduced	Little change slight tendency to round off	Quick recovery in fresh serum
1/200		Complete inhibition (time of observation 42 hours)	Cells grow smaller rounding off clumping	Morphological recovery in fresh serum is rapid mitotic activity also resumed but not immediately

The tests described were designed only to indicate the order of magnitude of the concentrations of penicillin which are significantly toxic to various types of living cell. These concentrations may be said to be not less than 1/5000 Significance can be attached to tissue-culture experiments with drugs only when they exert no secondary action, such as reaction with serum, high osmotic pressure or surface activity, which obscure an estimate of their specific toxicity Penicillin exerts no appreciable secondary reaction of this kind The preparations used in the experiments were therapeutic penicillin " and also an even more highly purified sample

Their actions in vitro proved to be identical and the figures quoted may be taken to refer to either

Dr F Jacoby, of the physiology department Birmingham University, has tested the effects of penicillin on hen's macrophages cultivated in vitro His results are presented in table II and fig 4

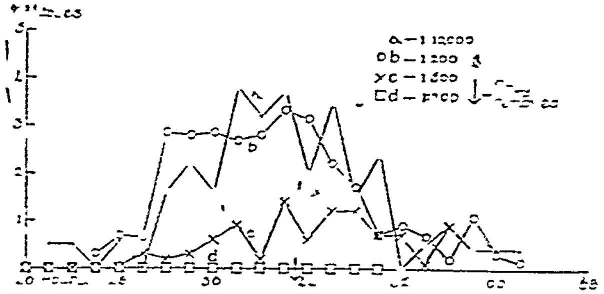

FIG 4—Effect of penicillin in various dilutions on hen s macrophages cultivated in vitro

It thus appears that penicillin is even less toxic to hen s macrophages than to fibroblasts and epithelium.

LOCAL APPLICATION

The effect of local application has been tried on the relatively delicate tissue of the central nervous system In two rabbits under Nembutal anæsthesia a needle was inserted into the cisternal space and when a few drops of clear cerebrospinal fluid had escaped a burette containing 1/1000 penicillin in normal saline was attached to the needle A slow intravenous injection of 11 c cm of 25% sodium chloride was then made, which caused rapid absorption of cerebrospinal fluid into the blood-stream with consequent indrawing of fluid from the burette into the cisternal space Weed (1922) showed that under the influence of this powerful osmosis the fluid introduced passed along the perivascular sheaths and even into the perineuronal spaces of the cerebral cortex In this instance 2 c cm of penicillin solution was drawn into the space in 23 minutes in one rabbit and 1 5 c cm. in 32 minutes in the other After the cisternal needle had been withdrawn and the anæsthetic had passed off neither rabbit showed the slightest functional disturbance Both were killed 6 days later, when histological examination of the brain by Dr Dorothy Russell showed that there was no meningitis or damage to the marginal glia and that the choroid plexuses and ependyma were everywhere normal Dr Russell investigated the effect on the brain in 3 other rabbits by methods she had previously described (Russell and Falconer 1941) and again no lesions attributable to the penicillin were discovered These results, taken in conjunction with those on leucocytes and on tissue cultures, strongly support the view that local application of quite strong solutions should prove innocuous to tissue cells

ABSORPTION AND EXCRETION OF PENICILLIN

It has previously been shown that penicillin is absorbed after subcutaneous injection in mice, and from the intestine in rats and that antibacterial activity appears in the urine secreted subsequently. Absorption and excretion have now been further investigated on rabbits, cats and man, always using the sodium salt of penicillin. The blood and urine levels have been compared after intravenous, subcutaneous and intestinal administration, often on the same animal As the substance loses activity quickly in acid solution it was not considered worth while at this stage to study the results of direct administration into the stomach except for two tentative observations on normal subjects and in Case 6 Absorption from the gastro-intestinal tract has mainly been studied by the direct introduction of penicillin into the duodenum through a small fistula In man a duodenal tube was used. The standard dose in all experiments on the rabbit and cat was 400 units Unless otherwise stated the urine was collected by catheter the bladder was washed out and the washings were added to the urine for assay When necessary a short ether anæsthetic was given to facilitate the injection and the collection of the urine

In rabbits—Rabbit 1 received two doses by each route After duodenal administration no detectable activity was large numbers of colonies on subculture The only trace of lethal effect that we observed was an acceleration of the death-rate of small numbers of streptococci in Ringer's fluid containing 1/50,000 penicillin, compared with the rate in pure Ringer's fluid

In its mode of action, penicillin resembles the bacteriostatic sulphonamide drugs, but on comparing their actions one becomes aware of the following important and significant differences

1 The bacteriostatic power of penicillin against streptococci and staphylococci is much greater than that of the sulphonamides, even when these substances are tested under optimal conditions (small inoculum, peptone-free media &c) Saturated watery solutions of sulphapyridine and sulphathiazole show no complete inhibition on an assay plate, whereas penicillin at 1/500 000 gives an appreciable clear zone

2 The action of penicillin on streptococci and staphylococci unlike that of the sulphonamides, is only influenced to a minor extent by the number of bacteria to be inhibited Even when the culture media are inoculated with several millions of staphylococci or streptococci per c cm of medium, the multiplication of these organisms may be completely inhibited by penicillin in a concentration as low as 1/1,000,000 With smaller inocula the inhibition will occur in even higher dilutions This property of penicillin is of great importance for the treatment of heavily infected wounds, on which the sulphonamide drugs seem to have but little beneficial action

3 The bacteriostatic power of penicillin against streptococci and staphylococci is not antagonised to any appreciable degree by hydrolytic protein breakdown products or products of tissue autolysis or pus, substances which annul completely the bacteriostatic action in vitro of the sulphonamide drugs This is again of great importance in the treatment of suppurating wounds and makes possible the successful treatment of infections in which abundant production of pus takes place

EFFECT OF PENICILLIN ON CELLS

LEUCOCYTES

There is little doubt that substances which are not bactericidal but only bacteriostatic depend to a considerable extent for their curative properties on the activity of the leucocytes which deal with the organisms while the latter are prevented from multiplying In tests on leucocytes "therapeutic penicillin" has been compared with some other bacteriostatic substances which are at present engaging attention both for general and local use

Technique —We are indebted to Dr C G Paine of The Jessop Hospital, Sheffield, for sending details of his technique for examining leucocytes His solution has been used, though his method for examining the leucocytes has been altered

Human leucocytes survive well in a solution containing urea 0 3 g , glucose 1 g , $NaHCO_3$ 1 61 g , NaH_2PO_4 H_2O 0 425 g , NaCl 4 95 g , KCl 0 625 g , $MgCl_2$ 0 24 g , $CaCl_2$ 0 31 g in a litre of distilled water, with 10% of serum added at the time of the experiment The test substance was dissolved in the salt solution and diluted serially, each dilution allowing for the addition of the serum The control consisted of salt solution and serum The leucocytes came from the same donor as the serum A drop of blood was allowed to clot on a coverslip and the coverslip incubated at 37° C for about 30 min in a Petri dish containing moist blotting paper The clot was picked off, the red blood cells washed away with warm salt solution and the coverslip reversed over a well-slide containing the test solution Many leucocytes stuck to the coverslip and could be examined under all powers of the microscope The slide and microscope stage were kept at 36°–37° C in a thermostatically controlled box

Penicillin, the flavines and the sulphonamides were obtained as dry powders and dissolved in the salt solution Hypochlorite was obtained as the concentrated stock solution of "electrolytic sodium hypochlorite " dispensed for clinical use, which contains 1% NaOCl Dilutions are given in terms of this solution, not of hypochlorite Albucid was provided as a 30% solution of the sodium salt (solvent not stated), this solution was diluted as usual, and the concentrations given are those of the pure substance To make concentrated solutions of sulphapyridine and sulphathiazole the substance was shaken with the salt solution for 2 or 3 hours at 37° C and the excess centrifuged off

The pH of the salt solution and of the final checked with brom-thymol-blue Albucid was found slightly acid even when buffered by serum Each was tested more than once , the results were always sistent A wide range of dilutions was used in most ments but only the significant results are reported

Results —Penicillin at a dilution of 1/100 leucocytes immediately , at 1/250 more than 50% for 4 hours—the longest time for which they watched—but the survivors were sluggish towards th The preparation at 1/500 was indistinguishable control

Proflavine (2 8-diaminoacridine hemisulphate) killed immediately at 1/20,000 and within 2 hours at 1/50,0 In 1/100,000 the leucocytes were sluggish after 2 hours but in 1/200,000 they were active for at least the same length of time In the lower dilutions the leucocytes became stained yellow immediately, at 1/100,000 by th end of an hour and at 1/200,000 by the end of 2 hours Leucocytes were killed immediately by 2 7 diamino-acridine monohydrochloride at 1/10,000 but at 1/20,00 they were active Albert, Francis, Garrod and Linnell (1938) found leucocytes fully active in both these substances at 1/8400 after 1 hour They mixed whole blood with the test solution on the coverslip and lowered a slide over to form a thin film Though the method was not the same as ours it is difficult to see where the discrepancy arises, unless the large amount of serum present inactivated the proflavine

The stock solution of hypochlorite diluted to 1/100 killed immediately After 2 hours the leucocytes in 1/500 were motile but sluggish compared with 1/1000 which equalled the control in activity

In 1/500 sulphanilamide after 2 hours, leucocytes showed only feeble pseudopod formation and no movement At 1/1000 their activity was less than the control a though all were alive Albucid gave a similar result a 1/500 and 1/1000 , 1/100 killed immediately and a 1/10,000 the leucocytes remained active for 2½ hours, th longest time for which they were watched Sulpha pyridine and sulphathiazole, being relatively insoluble were used in saturated solution At dilutions of 1/1 and 1/2 of the saturated solution neither inhibite immediately After 2 hours some of the leucocyte were dead in both the sulphapyridine preparations, the sulphathiazole preparations all were alive thoug some were inactive at 1/1 1

It appears therefore that the flavines are more toxi than was previously supposed (this finding is in agreement with recent tissue-culture studies) and are no suitable for repeated use in high concentration on suc lesions as burns The hypochlorite solution, which being used in 5% strength for washing burns, is al very lethal to leucocytes, though it may possibly b inactivated at the surface of the tissue The sulphonamides in general have little inhibitory effect on th leucocytes, which strengthens their value for loc application Penicillin is less toxic to leucocytes in vit than the sulphonamides and should make an admirabl local application for infected tissue surfaces Its gre solubility might lead to rapid removal by the blood stream, but only further tests can show whether this is Continuous irrigation or repeated application would any case overcome the difficulty

The fact that penicillin at 1/500 does not appear t embarrass leucocyte activity in vitro contrasts with i complete bacteriostatic effect on staphylococci an streptococci in vitro at dilutions of at least 1/1,000,00 It is clear that leucocytes will remain completely active any concentration of penicillin likely to be reached aft intravenous injection

TISSUE CULTURE

Complementary to these experiments on leucocytes a those done on tissue cultures by Dr P B Medawar of t Zoology Department, who has kindly allowed us include his results here

Technique —The method employed had been devised for t determination of the inhibitory power of drugs (Medaw 1940, Jacoby, Medawar and Willmer 1941) It takes advanta of the fact that tissues freshly explanted into a medium blood plasma diluted with saline when incubated at body te perature show a characteristic power of resistance to grow inhibition which depends on the source and cellular composit ivated in the body, it was clear that frequent doses ld be necessary At the outset it was felt that rmittent administration might give the best diffu- into the tissues as a result of the repeated tem- ry raising of the concentration of the drug in the d above the highest level that could be attained by tinuous administration of the same total quantity facilitate frequent injections a cannula was tied or a dle inserted into a vein and connected to a slow drip paratus (Marriott and Kekwick 1940) which delivered teady flow of 500 c cm of 1 05% sodium citrate 0 8% sodium chloride in 24 hr Each dose of icillin was dissolved in about 2 c cm of non-pyrogenic ter, injected into the rubber tubing of the drip paratus and flushed in with a little of the citrate-saline lution This method is admittedly inconvenient owing the well-known difficulties of maintaining an intravenous infusion for ore than two or ree days, but it as thought that the therapeutic fficacy of penicillin could be stablished by this method other ways of giving the drug could then be explored

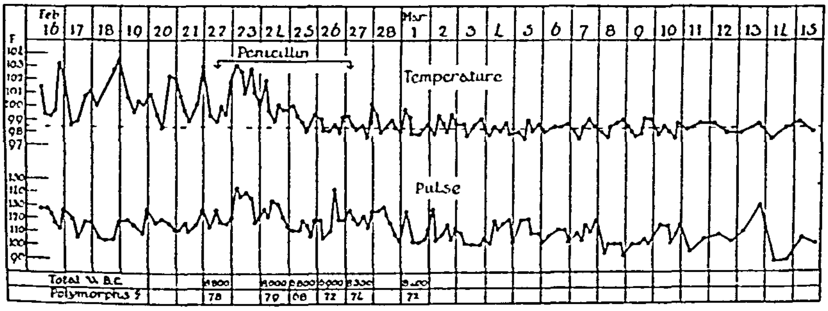

FIG 5—Chart and white cell counts in case 2

In case 5 the effect of running in a continuous supply of penicillin solution was tried At first a dilution of 1/1000 in normal saline was used, and as this was found to be no more harmful to the vein than normal saline alone the concentration was raised to 1/500 The vein tolerated this concentration well Higher concentrations have not been tried It is probable that this method of intravenous medication is the simplest and most useful

Administration by the mouth is complicated by the fact that penicillin is rapidly destroyed by acid and therefore serious losses are to be expected in the stomach It may however be possible to carry the penicillin through the stomach by raising the pH of the gastric contents Experiments with such substances as magnesium trisilicate or the recently described aluminium phosphate (Fauley et al 1941) are clearly required In case 6 a strongly antibacterial concentration of the drug was maintained in the urine for 7 days by giving it by mouth together with sodium bicarbonate In this case however we were aiming at keeping up an antibacterial concentration only in the urinary tract, and not in the blood The possibility of administration in capsules which will pass through the stomach has not been overlooked, but some tentative experiments with salol-coated capsules were discouraging Moreover, Cook and LaWall (1936) stated that only 10% of such capsules passed through the stomach satisfactorily ; we have therefore not thought it worth while to entrust a scarce and valuable substance to such unreliable vehicles Rectal administration was tried in one subject, but very little active substance was recovered in the urine and it was afterwards found that fæces inactivate penicillin, probably by bacterial action It was thought undesirable to introduce very strong solutions of penicillin subcutaneously or intramuscularly owing to uncertainty about the local effects More dilute solutions, for example 1 in 500, which have been shown to be innocuous to leucocytes, would involve the use of excessive amounts of fluid In case 1 the injection of 100 mg in 2 c cm of water intramuscularly caused some tenderness, though this cleared up quickly

INTRAVENOUS ADMINISTRATION IN STAPHYLOCOCCAL AND STREPTOCOCCAL INFECTIONS

CASE 1 —Policeman, aged 43 Admitted Oct 12, 1940 Suppuration of face, scalp and both orbits, starting from a sore at the corner of the mouth a month earlier Primary infection *Staph aureus*, secondary, *Strep pyogenes* Sulphapyridine 19 g given from Dec 12 to 19, no improvement, drug rash Jan 19 incision of multiple abscesses on face and scalp Osteomyelitis of right humeral head, proved by X rays, showed on Jan 31, 1941, after 3 weeks of pain, a resulting arm abscess, incised, gave *Staph aureus* pus General infection of left eye, cornea perforated Jan 21 Eye eviscerated Feb 3 Blood-transfusion 2 pints Feb 9 Fever intermittent all this time, 98°–101° F Very ill and emaciated, tongue heavily furred Feb 11 right eye bulging and conjunctival chemosis, orbit incised, pus gave *Staph aureus* and *Strep pyogenes*

Feb 12 all incisions suppurating, in scalp, face, both orbits, and right arm Lungs involved, with purulent expectoration containing both the pyogenic cocci Hb 36%, red cells 1,800,000 Blood culture sterile Penicillin 200 mg given intravenously, then 100 mg 3 hourly, intravenous except for two intramuscular doses Slight rigor after first dose, otherwise no reactions Striking improvement after total of 800 mg penicillin in 24 hours Cessation of scalp-discharge, diminution of right eye suppuration and conjunctivitis Arm discharge seemed less Blood tests just before injections for penicillin 7 30 A M faint trace, 11 30 A M none Feb 13 penicillin 100 mg intravenously 4-hourly Feb 14 condition much the same Blood-transfusion 3 pints Penicillin 100 mg 2 hourly by injection into transfusion tube, total 1 g in 24 hours Feb 15 1 pint blood transfused and penicillin 100 mg given 3-hourly, most of which had been recovered from previous urine Feb 16 much improvement, Hb 74% Right eye almost normal Some discharge still from left eye and arm Shortage of penicillin interrupted treatment from noon to 6 P M, then drip infusion of sodium chloride and citrate, penicillin 200 mg being injected into drip, then 100 mg 3 hourly, no reaction Feb 17 penicillin supply exhausted Total administered, 4 4 g in 5 days Patient felt much improved, no fever, appetite much better, resolution of infections in face, scalp and right orbit, still coughing, sputum contained *Strep pyogenes* and *N catarrhalis* Left orbit and right humerus still suppurating Blood urea 30 mg per 100 c cm, urine normal Condition stationary for 10 days, then deteriorated, especially lungs March 15 died Autopsy showed typical picture of staphylococcal pyæmia with multiple abscesses

White counts—Feb 12, 20,000 (polymorphs 88%), 13th, 19,000, 14th, 11,200, 15th, 16,800, 18th, 8400, 19th, 7600, 20th, 7600 (polymorphs 84%), 25th, 8000, March 5, 11,000 (polymorphs 88%)

The attempt to treat this forlorn case was chiefly valuable in that it showed that penicillin could be given over a period of 5 days without significant toxic effect There was a fall in the total white count, but both granular and agranular cells were equally affected Apart from this effect, which has not been seen in subsequent cases, and the slight rigor due to a pyrogenic impurity in the penicillin, no contra-indications to its use were observed Assessment of its effect was difficult since a blood-transfusion was given at the same time, and later experience showed that the dose of penicillin employed was too small, and the period of administration too short None the less the superficial sepsis responded well, and did not relapse after the penicillin was stopped

CASE 2 —Boy, aged 15 Admitted Dec 29, 1940, for slipped right femoral epiphysis Open reduction with insertion of Smith-Petersen pin Jan 24, 1941 Severe post-operative hæmorrhage followed by infection of wound with hæmolytic streptococcus (group A, type 13), positive blood-culture Wound reopened and patient given Proseptasine from Jan 25 to Feb 3, two courses of 5 g sulphapyridine soluble intravenously in 30 hours on Feb 7th and 9th, and two blood-transfusions, but swinging temperature (99°–103° F) continued (see fig 5)

Feb 22 looked ill, pale and wasted, two granulating areas over right hip, discharging sero-pus Hb 62%, red cells 3,000,000, white cells 8800 (polymorphs 78%) Blood-culture sterile Blood urea 32 mg per 100 c cm Urine normal At noon 100 mg penicillin injected into intravenous drip infusion of citrate saline, repeated 2 hourly for 8 hours After interval of 3 hours given another 100 mg producing observed in the blood after ½ hr (one experiment) or 1 hr (2 experiments), 14% and 5 3% respectively of the active substance were excreted in the urine Similarly after intravenous injection there was no activity in the blood at 1 hr 20 min and 1 hr 50 min in one experiment, or at ½ hr, 1 hr and 1½ hr in another, the yields in the urine were greater, however, being 44% and 24% Subcutaneous injection produced a trace of activity in the blood in the two samples taken—at ½ hr in one experiment and 1 hr in the other, 40% and 14 5% were recovered from the urine

One rabbit after a duodenal injection showed no activity in the blood at 1 and 2 hr and none in the urine, but since the urine was passed naturally in a metabolism cage during the night activity may have been lost by bacterial action, in spite of the presence of chloroform

In a third rabbit the standard dose was injected into the intestine in an acute experiment On the supposition that penicillin might be absorbed from the gut and then inactivated in the liver, samples were drawn from the portal vein and the vena cava at 10, and later 20, minute intervals for 1½ hr In no blood sample could activity be detected, but the urine at the end of 2½ hr contained 12% of the injected penicillin Bile from a cannula in the common duct (the cystic duct having been tied) consistently showed a trace of activity up to 2½ hr, the end of the experiment In a fourth rabbit, also under nembutal, the penicillin was injected intravenously and blood taken from the ear vein There was no activity in 4 half hourly blood samples and a trace in the first bile sample only, but the urine samples were active A repetition of this experiment on a fifth rabbit gave essentially the same result The rabbit, therefore, gives a good return in the urine after intravenous injection (20–50%), but a return of less than 20% after administration into the intestine Penicillin can almost never be detected in the blood at ½ hr by whatever route it is given There is some excretion in the bile Because activity cannot be shown in the blood these experiments do nothing to decide whether the greater "loss" which appears to be associated with intestinal administration occurs before, during or after absorption

Cats—Cat 1 was equivalent to rabbit 1, receiving the standard dose of penicillin by three routes After intestinal injection a trace was detectable in the blood at ½ and 1 hr (2 experiments) and at 1½ hr (1 experiment) and the urine contained 60% of the active substance (1 experiment) Similarly after intravenous and subcutaneous injection activity was observed in the blood at ½ and 1½ hr, and the urine showed 33% and 52% of the activity respectively In the blood of cat 2, taken half hourly for 3 hours after a duodenal injection, activity could not be detected in the first sample but was seen in all the rest, rising to the end of the second hour and then falling again

Cat 3 was anæsthetised with nembutal and the bile duct cannulated, the cystic duct having been tied Penicillin was injected into the duodenum Activity could just be detected in the portal and vena caval blood in samples taken every 15 min for ¾ hr The bile had no activity in the first 15 min, a little in the second and a high titre was maintained during the second hour, at the end of which the experiment was stopped A similar experiment on cat 4 showed activity in the systemic blood for 3¼ hr, with a trace until 4½ hr, and in the bile and urine throughout the 6 hours of the experiment Excretion in the bile reached its peak at 3½ hr and then fell away, in the urine it showed a small decline after the 4th hour

Cat 5 was decerebrated and prepared in a similar way and here the injection was given intravenously Penicillin was excreted by the liver for the whole 6 hours of the experiment (only a trace in the last hour) but since little bile was secreted the total amount was small Half of the active substance was excreted in the urine in the 6 hours In cat 6, anæsthetised with chloralose, the investigation was extended by producing a flow of saliva and tears with pilocarpine, and of pancreatic juice with secretin Penicillin given intravenously was excreted in high concentration in the bile for the first three hours, slightly in the fourth hour and not at all in the fifth It was secreted also in the saliva, but here the concentration was lower than in blood collected at the same time It was present in the blood for 1½ hr Tears and pancreatic juice showed no activity Half of the penicillin was excreted in the urine in the 5 hours of the experiment Cat 7 prepared in the same way gave a similar result, but the experiment was stopped at the end of an hour to collect the cerebrospinal fluid, which proved to be inactive Controls showed that bile alone was inactive on the assay plate and that pancreatic juice did not destroy penicillin activity

These experiments show that the cat differs from the in maintaining an antibacterial concentration of the blood for at least 1½ hr after subcutaneous or injection and at least 3 hr after intestinal administration differs also—and the two facts are no doubt connec excreting in the urine about 50% of the penicillin, even injected by the intestinal route

In man—Subcutaneous injection has not been used in but from preliminary observations and from the treated a good deal has been learned about the blood level urinary excretion reached after both intravenous and in testinal administration Trials with ascending doses of "therapeutic penicillin" showed that a single intravenous injection of 200 mg could be given without ill effect This is the largest single dose which has been given The inhibitory power of the blood was followed in one subject at frequent intervals from 5 min until 2 hr 5 min after the injection The high initial value gradually fell to a just discernible trace in the last sample Urinary excretion was still occurring at 6 hr 15 min and there was a trace of inhibition in a sample of urine collected from the 6th to the 14th hour After a dose of 100 mg inhibition was just detectable in the blood at the end of an hour After repeated 100 mg doses a trace of inhibition was similarly found in the blood one hour after an injection (case 3, who had had five initial hourly doses of 200 mg) The best experiments from the point of view of estimating the urinary recovery after intravenous injection were those on patients No 3 and 5, whose urine output was accurately measured during the course of treatment In case 3 about 50% of the total active substance injected was present in the urine and 30% was actually recovered in purified form (the rest being lost in the re-extraction process) In case 5, in which penicillin dissolved in saline was administered continuously, 68% of the antibacterial activity reappeared in the urine and 54% was recovered for further use

For duodenal administration a tube was passed and its location in the duodenum confirmed by fluoroscopy Sixteen thousand units (about 400 mg of the solid material) dissolved in 25 c cm of water were injected down the tube, followed by 60 c cm more of water After this injection the blood inhibited bacterial growth for 3 hr and urinary excretion continued for 6 hr The inhibitory level in the blood was steadier and persisted for a longer time than after intravenous injection The dose was twice the maximum so far given intravenously and it is quite possible that larger doses will always be needed for treatment by the intestinal route Nevertheless the indications are that this is a possible way of administering penicillin

A contrast thus emerges between the behaviour towards penicillin of the rabbit on the one hand and of the cat and man on the other After giving 400 units intravenously to a rabbit no activity could be detected in the blood at the end of half an hour, while in the cat after the same dose the blood was active for at least 1½ hr Similarly after duodenal introduction, there was no activity in the blood and little in the urine of the rabbit, whereas in the cat activity could be detected in the blood and there was a considerable excretion in the urine Man appears to be in both instances more like the cat than the rabbit Apparently the rabbit has a more effective mechanism for the inactivation of penicillin than either of the other two species

By whatever route penicillin is administered not all the active substance appears in the urine Where this "loss" occurs is not yet clear Incubation for 3 hr at 37° C of penicillin with blood and with slices of liver, kidney, spleen, brain, muscle, lymph-gland, lung and intestine from the rabbit caused no detectable destruction Nor was there any diminution of activity after incubation with rabbit-bile, though there was perhaps a slight fall with cat-bile It is impossible to say whether the material recovered from the urine has been changed in any way during its passage through the body It has a high antibacterial titre and has been used again for injection into patients without ill effect It is of interest to note that material partially purified but containing pyrogen is freed from that impurity by passage through the body

THERAPEUTIC TRIAL OF PENICILLIN

Methods of administration—To avoid the uncertainties of intestinal absorption, the first cases were treated by penicillin given intravenously Since it is rapidly eliminated by the kidneys and probably partially cyte , this tissue is well vascularised and there is some blastic proliferation, greatest in the periphery In the mous region some of the veins contain organising throm- , the left carotid and vertebral arteries show organising mbi which do not appear to be infected, but as there are e breaks in the media and elastica of the walls of both these els it must be presumed that they are the late results of an te arteritis probably of bacterial origin The other organs w no significant change

he autopsy showed that the infection in the cavernous as, orbits and in the lungs had been almost entirely rcome, and that healing processes were well advanced ath was due to the ruptured mycotic aneurysm and to a recrudescence of the infection Before this scular accident the patient had been restored from a mbund condition to apparent convalescence No ic effects from the penicillin were noticed

CASE 5 —Boy, aged 14½ Admitted May 6, 1941 Staphylo ccal septicæmia with early osteomyelitis of left femur llowing fall 6 days before Blood culture grew *Staph reus* Given sulphathiazole 64 g between May 7 and 12 ith little benefit May 17 left hip joint explored, no bscess found, joint contained little sterile fluid with polymorphs in it May 22 blood and albumin in urine Embolic ustular rash Extension by skin traction applied to left leg ay 30 X rays showed osteitis left femoral neck with nvolvement of joint and destruction of alveolar walls Dis charge from wound grew *Staph aureus*

June 6 still extremely ill, with temperature rising to 101° F , much pain in left hip and thigh , urine still contained blood and albumin Hb 74% , red cells 4,290,000 Blood urea 23 mg per 100 c cm Intravenous infusion of 500 mg

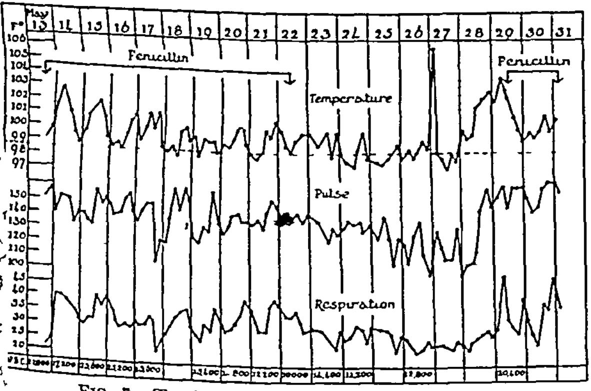

FIG 7—Chart and white cell counts in case 4

enicillin in 540 c cm normal saline started at 45 c cm an our Infusion continued for 90 hours during which time 5 g penicillin given No reaction Daily tests showed onstant bacteriostatic concentration in blood General ondition much improved By June 10 had lost almost all ain and tenderness Cannula transferred to another vein nd infusion continued at half rate with double strength of enicillin (1 g in 500 c cm) On June 11 and 13 sudden rises f temperature without apparent cause , traced to use of enicillin prepared 2 months previously and containing yrogenic impurity June 14 cannula transferred to nother vein and penicillin recovered from boy's urine used o further rise of temperature Steady improvement On une 16 continuous administration stopped Given another 0 mg 3 hourly for 12 doses and then 4 hourly for 12 more oses Stopped June 20 , total dosage 17 2 g Urine then ormal Blood urea 29 mg per 100 c cm June 21 Hb 64%, ed cells 3,750,000 June 23 radiograms of hip showed no xtension of destructive process , boy felt quite well July 9 xtension removed July 11 had been afebrile for 3½ weeks o pain in leg Passive hip movements, flexion 80° Other ovements almost full

White counts —June 6, 9400 , 8th, 9700 , 9th, 11,800 , 0th, 13,800 , 11th, 11,400 , 12th, 7500 , 13th, 9400 , 14th 6,400 , 15th, 10,400 , 16th, 8400 , 17th, 7600 , 18th, 6200 , 0th, 11,800 , 21st, 12,400

This was a case of staphylococcal septicæmia, localising the left hip-joint, which had been uninfluenced by rge doses of sulphathiazole in the early stages When nicillin was started the boy was extremely ill, in great ain, and had an active nephritis. As in the other cases ere was a striking improvement in the general condition during the period of therapy All pain in the region of the left hip disappeared, the nephritis cleared and his temperature fell to normal At the time of writing it had remained normal for 3½ weeks and there was good function in the hip

ORAL ADMINISTRATION IN URINARY INFECTION

CASE 6 —Boy, aged 6 months Admitted April 8, 1941 Ill a fortnight with diarrhœa and vomiting, melæna and general ised convulsions Dehydrated, few petechiæ in skin Red cells 1,560,000 , white cells 28,000 (atypical lymphocytes 50%, many primitive cells) Blood urea 60 mg per 100 c cm Urine contained albumin and pus , grew *Staph aureus* and *Bact coli* Sulphapyridine tried but stopped because polymorphs fell to 400 per c mm After fortnight's course of ammonium mandelate urinary infection remained June 3 urine grew pure *Staph aureus* Hb 62% , red cells 3,200,000, white cells 5000 (polymorphs 600) Blood urea 66 mg per 100 c cm June 5 attempts to pass duodenal tube failed, so penicillin given by mouth , 20 mg with 2 g sodium bicarbonate given hourly for 3 doses and then 3 hourly No toxic signs Vomited once, which was not unusual All specimens of urine contained strongly bacteriostatic concentration of penicillin June 7 urine contained no pus cells , penicillin reduced to 10 mg 3 hourly Vomited 2–3 times daily Steady general improvement June 9 polymorphs up to 1000 per c mm , blood-urea 46 mg per 100 c cm June 12 penicillin stopped June 17 blood urea 39 mg per 100 c cm , Hb 70% , white cells 4000 (polymorphs 440) June 19 urine sterile though still containing heavy cloud of albumin and occasional casts and red cells General condition continued to improve June 26 urine still free from *Staph aureus*

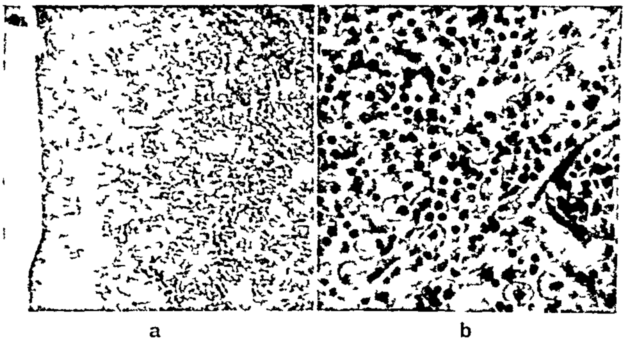

FIG 8—(*a*) Low power view (×40) Wall of " abscess cavity in the lung showing the œdema fluid rich in lipoid containing histiocytes and the wall made up of a vascular granulation tissue in which there are large numbers of lipoid containing histiocytes, lymphocytes and plasma cells and only a few neutrophil leucocytes At the extreme right of the section the normal lung parenchyma can be seen

(*b*) High power view (× 180) Granulation tissue from the left orbital region showing the characteristics of the cellular reaction a mixture of lipoid containing histiocytes lymphocytes and plasma-cells, and a moderate fibroblastic proliferation

This case demonstrates that it is possible to maintain a bacteriostatic concentration of penicillin in the urine with small doses given by mouth Although the diagnosis was obscure there was no doubt of the urinary infection by *Staph aureus*, and the administration of penicillin overcame this infection

LOCAL APPLICATION TO THE EYE

In case 4 a 1/5000 solution of penicillin in normal saline was applied to a corneal ulcer It caused no irritation and the condition of the eye improved The local application of penicillin in other eye infections was therefore tried on patients in the Oxford Eye Hospital

CASE 7 —Married woman, aged 32 Had a corneal ulcer of the left eye 4 months previously, treated successively by instillation of Collosal Argentum, boracic lotion and mercurochrome, and ultraviolet light In 6 weeks ulcer resolved completely, but 3 weeks later similar ulcer developed in right eye Treated on similar lines, for 6 weeks as outpatient and then for fortnight as inpatient, but without improvement May 26, 1941 infiltrating ulcers in inner and upper quadrants of limbus, gross injection of conjunctiva and considerable corneal opacity Swab from eye grew *Staph aureus*

May 30 treatment with penicillin begun , 1/5000 solution in normal saline dropped into eye hourly by day and 2 hourly slight rigor, then 75 mg 3 hourly Feb 24 general condition better, discharge less By 9 P M had received 1 4 g penicillin, dose raised to 100 mg 3 hourly, using a purer penicillin, no reaction Feb 27 penicillin stopped, total 3 4 g Three blood examinations just before injections had only once shown slight antibacterial activity Feeling better, local condition unchanged Blood urea 29 mg per 100 c cm Urine normal White cells 8300 (polymorphs 74%) Feb 25 blood transfusion 2 pints Feb 26 plaster spica applied After 3–4 weeks of almost normal temperature pin removed Again developed swinging temperature as before penicillin treatment

Several different samples of penicillin were used in this case The first five doses had been recovered from the urine of case 1 and caused no reaction The next samples, which caused some shivers, were "third fraction," and although they had been passed through an absorption column again they still contained the pyrogen The later doses were "second fraction" (our present "therapeutic penicillin") Here there was a local infection by a hæmolytic streptococcus which had proved resistant to sulphanilamide in large doses and to moderate doses of sulphapyridine Penicillin therapy was followed by a great improvement in the patient's general condition, in spite of the dose being insufficient to maintain a detectable concentration of penicillin continuously in the blood

CASE 3—Labourer, aged 48, of poor physique Admitted May 2, 1941 Carbuncle 4 in across over left scapula for 5 days, now discharging, pus grew pure *Staph aureus* History of chronic bronchial and nasal catarrh for 4 months Left axillary adenitis Hb 106%, red cells 4,970,000, white cells 23,000 Blood urea 31 mg per 100 c cm Urine normal

May 3 penicillin 200 mg hourly for 5 doses by injection into intravenous drip as in case 2, then 100 mg hourly No reaction Antibacterial activity continuously maintained in blood May 7 carbuncle much improved, slight tenderness, only slight serous discharge Dose dropped to 100 mg 2 hourly and then 3 hourly May 10 carbuncle almost completely resolved, no axillary adenitis, bronchial and nasal catarrh cleared, 100 mg penicillin 6 hourly for 4 doses and then stopped May 11 Hb 90%, red cells 4,970,000, white cells 15,800 Blood urea 37 mg per 100 c cm Urine normal Temperature, which had been swinging 97°–101° F now normal and remained so Local treatment had consisted in kaolin poultice for first 48 hours, sodium sulphate dressing for next 48 hours and subsequently dry dressing May 15 discharged Seen as outpatient on May 19 when skin over carbuncle almost normal and patient generally well, right ulnar neuritis which cleared quickly, possibly from splinting arm for several days during infusion

White counts—May 3, 23,000 (polymorphs 87%), 5th, 16,400, 6th, 15,200, 7th, 7800, 8th, 9200, 9th, 19,200, 10th, 19,800, 11th, 15,800

In this case the supply of penicillin was sufficient to enable a detectable concentration of penicillin to be maintained continuously in the blood for the first 4 days There was no toxic effect from the larger dosage The result was a rapid resolution of the carbuncle without its discharging and without scar formation In addition the chronic nasal and bronchial catarrh were cleared The white count was temporarily depressed on the 4th and 5th days but rose again in spite of the drug being continued

CASE 4—Boy, aged 4½ years Admitted May 13, 1941 Cavernous sinus thrombosis from septic spots on left eyelid and face following measles 5 weeks before Had received 30 g sulphapyridine in 14 days before admission Semicomatose, incontinent of urine and fæces Gross œdema both eyelids (fig 6a), especially left, with bilateral proptosis Complete bilateral external ophthalmoplegia and 2 dioptres of papillœdema, neck rigidity, bilateral Kernig's sign and extensor plantar responses Moist sounds both bases Liver edge two finger breadths below costal margin Blood culture sterile Lumbar puncture gave a faintly yellow cloudy fluid under high pressure (see table III)

May 13 intravenous infusion of citrate saline at 10 c cm an hour (rate maintained with slight variations for 9 days, the site of infusion being changed 4 times) Penicillin injected into infusion, dose 100 mg hourly for two doses, 50 mg hourly for four doses, then 25 mg hourly May 14 pus from incision made into left eyelid and swab from nose grew *Staph aureus* X ray opacity of left antrum, ethmoid clear May 15 blood sample an hour after dose of penicillin showed no antibacterial activity, dose increased to 50 mg hourly General improvement May 16 obviously better swelling of eyelids largely subsided Blood taken just before injection showed trace of antibacterial activity May 19 general and local condition vastly improved (see fig 6b), bilateral 6th nerve palsy and extensor plantar responses remained Penicillin reduced to 50 mg 3 hourly Small corneal ulcer left eye treated with penicillin 1 in 5000, which caused no discomfort May 22 improvement maintained, patient talking and playing with toys *Chest clinically* normal Slight pyrexia still thought to be due to pyrogen in penicillin or to reaction from thromboses in veins used for injections (see fig 7) Penicillin stopped May 26 progress good Temperature normal General condition excellent Eye movements returning X ray of sinuses only slight clouding left antrum, chest, patch of consolidation left apex and small ring shadow right mid zone These thought to be embolic signs but general condition so good that no further penicillin needed May 27 1 A M vomited and had general convulsions Lumbar puncture gave uniformly blood stained fluid under high pressure Became comatose with neck rigidity, positive Kernig's sign and spastic limbs May 28 temperature began to rise again May 29 appearance much as on admission Penicillin 2 g given in next 36 hours, but died May 31

TABLE III—CEREBROSPINAL FLUID OF CASE 4

* Cell count done after fluid had stood for several hours

Autopsy (Dr A H T Robb Smith)—Brain showed no thrombosis of main venous sinuses, adhesions and old hæmorrhage in hypophysial region Considerable old and recent hæmorrhage in region of pons and cerebellum due to rupture of aneurysm on left vertebral artery Cavernous sinus region and left orbit occupied by œdematous granulation tissue, left carotid artery partially occluded by thrombus in its cavernous course and completely occluded in its bony course Both lungs showed scattered abscess cavities, larger ones being air containing cysts lined by yellowish membrane, smaller ones containing yellowish material not exactly resembling pus Other organ not remarkable

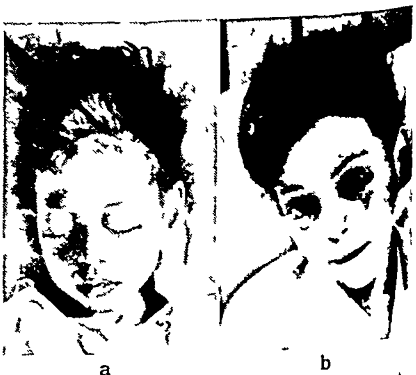

FIG 6—Case 4 (*a*) at beginning of treatment, (*b*) on 11th day of treatment

Histologically granulation tissue is essentially similar whether in lung abscesses, orbital tissues or cavernous region (fig 8) There is a small central area of necrosis sometimes containing a few gram positive cocci, around this is an œdematous exudate with lipoid containing histiocytes, surrounding this is a granulation tissue formed largely of histiocytes containing lipoid and blood pigment, lymphocytes and plasma cells with a very occasional neutrophil ucocyte, this tissue is well vascularised and there is some roblastic proliferation, greatest in the periphery In the vernous region some of the veins contain organising throm is, the left carotid and vertebral arteries show organising rombi which do not appear to be infected, but as there are rge breaks in the media and elastica of the walls of both these essels it must be presumed that they are the late results of an cute arteritis probably of bacterial origin The other organs ow no significant change

The autopsy showed that the infection in the cavernous inus, orbits and in the lungs had been almost entirely vercome, and that healing processes were well advanced eath was due to the ruptured mycotic aneurysm and ot to a recrudescence of the infection Before this ascular accident the patient had been restored from a oribund condition to apparent convalescence No oxic effects from the penicillin were noticed

CASE 5—Boy, aged 14½ Admitted May 6, 1941 Staphylococcal septicæmia with early osteomyelitis of left femur following fall 6 days before Blood-culture grew *Staph aureus* Given sulphathiazole 64 g between May 7 and 12 with little benefit May 17 left hip-joint explored, no abscess found, joint contained little sterile fluid with polymorphs in it May 22 blood and albumin in urine Embolic pustular rash Extension by skin traction applied to left leg May 30 X rays showed osteitis left femoral neck with involvement of joint and destruction of alveolar walls Discharge from wound grew *Staph aureus*

June 6 still extremely ill, with temperature rising to 101° F, much pain in left hip and thigh, urine still contained blood and albumin Hb 74%, red cells 4,290,000 Blood-urea 23 mg per 100 c cm Intravenous infusion of 500 mg penicillin in 540 c cm normal saline started at 45 c cm an hour Infusion continued for 90 hours during which time 3 5 g penicillin given No reaction Daily tests showed constant bacteriostatic concentration in blood General condition much improved By June 10 had lost almost all pain and tenderness Cannula transferred to another vein and infusion continued at half rate with double strength of penicillin (1 g in 500 c cm) On June 11 and 13 sudden rises of temperature without apparent cause, traced to use of penicillin prepared 2 months previously and containing pyrogenic impurity June 14 cannula transferred to another vein and penicillin recovered from boy's urine used No further rise of temperature Steady improvement On June 16 continuous administration stopped Given another 50 mg 3 hourly for 12 doses and then 4-hourly for 12 more doses Stopped June 20, total dosage 17 2 g Urine then normal Blood urea 29 mg per 100 c cm June 21 Hb 64% red cells 3,750,000 June 23 radiograms of hip showed no extension of destructive process, boy felt quite well July 9 extension removed July 11 had been afebrile for 3½ weeks No pain in leg Passive hip movements, flexion 80° Other movements almost full

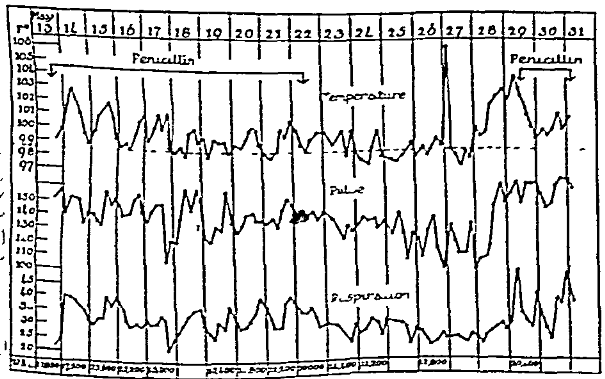

FIG 7—Chart and white-cell counts in case 4

White counts—June 6, 9400, 8th, 9700, 9th, 11,800, 10th, 13,800 11th 11 400, 12th, 7500, 13th, 9400, 14th 16,400 15th, 10 400, 16th, 8400, 17th, 7600, 18th, 6200, 20th, 11,800, 21st, 12,400

This was a case of staphylococcal septicæmia, localising in the left hip-joint, which had been uninfluenced by large doses of sulphathiazole in the early stages When penicillin was started the boy was extremely ill, in great pain, and had an active nephritis. As in the other cases there [illegible]king improvement in the general condition during the period of therapy All pain in the region of the left hip disappeared the nephritis cleared and his temperature fell to normal At the time of writing it had remained normal for 3½ weeks and there was good function in the hip

ORAL ADMINISTRATION IN URINARY INFECTION

CASE 6—Boy, aged 6 months Admitted April 8, 1941 Ill a fortnight with diarrhœa and vomiting, melæna and generalised convulsions Dehydrated, few petechiæ in skin Red cells 1,560,000, white cells 28,000 (atypical lymphocytes 50% many primitive cells) Blood urea 60 mg per 100 c cm Urine contained albumin and pus, grew *Staph aureus* and *Bact coli* Sulphapyridine tried but stopped because polymorphs fell to 400 per c mm After fortnight's course of ammonium mandelate urinary infection remained June 3 urine grew pure *Staph aureus* Hb 62%, red cells 3,200,000, white cells 5000 (polymorphs 600) Blood urea 66 mg per 100 c cm June 5 attempts to pass duodenal tube failed, so penicillin given by mouth, 20 mg with 2 g sodium bicarbonate given hourly for 3 doses and then 3 hourly No toxic signs Vomited once, which was not unusual All specimens of urine contained strongly bacteriostatic concentration of penicillin June 7 urine contained no pus cells, penicillin reduced to 10 mg 3 hourly Vomited 2–3 times daily Steady general improvement June 9 polymorphs up to 1000 per c mm, blood urea 46 mg per 100 c cm June 12 penicillin stopped June 17 blood-urea 39 mg per 100 c cm, Hb 70%, white cells 4000 (polymorphs 440) June 19 urine sterile though still containing heavy cloud of albumin and occasional casts and red cells General condition continued to improve June 26 urine still free from *Staph aureus*

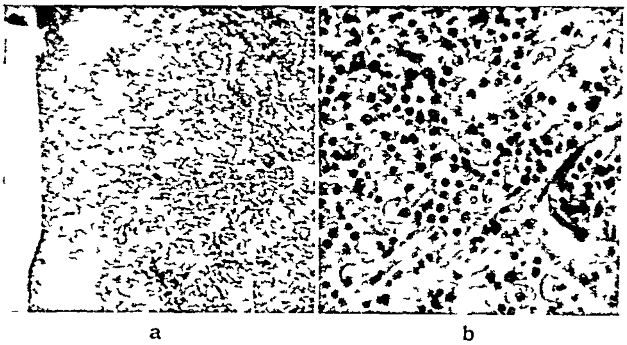

FIG 8—(*a*) Low power view (×40) Wall of "abscess cavity" in the lung showing the œdema fluid rich in lipoid containing histiocytes and the wall made up of a vascular granulation tissue in which there are large numbers of lipoid-containing histiocytes lymphocytes and plasma-cells and only a few neutrophil leucocytes At the extreme right of the section the normal lung parenchyma can be seen

(*b*) High power view (× 180) Granulation tissue from the left orbital region showing the characteristics of the cellular reaction a mixture of lipoid containing histiocytes lymphocytes and plasma-cells, and a moderate fibroblastic proliferation

This case demonstrates that it is possible to maintain a bacteriostatic concentration of penicillin in the urine with small doses given by mouth Although the diagnosis was obscure there was no doubt of the urinary infection by *Staph aureus*, and the administration of penicillin overcame this infection

LOCAL APPLICATION TO THE EYE

In case 4 a 1/5000 solution of penicillin in normal saline was applied to a corneal ulcer It caused no irritation and the condition of the eye improved The local application of penicillin in other eye infections was therefore tried on patients in the Oxford Eye Hospital

CASE 7—Married woman, aged 32 Had a corneal ulcer of the left eye 4 months previously, treated successively by instillation of Collosal Argentum, boracic lotion and mercurochrome, and ultraviolet light In 6 weeks ulcer resolved completely, but 3 weeks later similar ulcer developed in right eye Treated on similar lines, for 6 weeks as outpatient and then for fortnight as inpatient, but without improvement May 26 1941 infiltrating ulcers in inner and upper quadrants of limbus, gross injection of conjunctiva and considerable corneal opacity Swab from eye grew *Staph aureus*

May 30 treatment with penicillin begun, 1/5000 solution in normal saline dropped into eye hourly by day and 2 hourly slight rigor , then 75 mg 3 hourly Feb 24 general condition better, discharge less By 9 P M had received 1 4 g penicillin , dose raised to 100 mg 3 hourly, using a purer penicillin , no reaction Feb 27 penicillin stopped , total 3 4 g Three blood examinations just before injections had only once shown slight antibacterial activity Feeling better , local condition unchanged Blood urea 29 mg per 100 c cm Urine normal White cells 8300 (polymorphs 74%) Feb 25 blood transfusion 2 pints Feb 26 plaster spica applied After 3–4 weeks of almost normal temperature pin removed Again developed swinging temperature as before penicillin treatment

Several different samples of penicillin were used in this case The first five doses had been recovered from the urine of case 1 and caused no reaction The next samples, which caused some shivers, were " third fraction," and although they had been passed through an absorption column again they still contained the pyrogen The later doses were " second fraction " (our present " therapeutic penicillin ") Here there was a local infection by a hæmolytic streptococcus which had proved resistant to sulphanilamide in large doses and to moderate doses of sulphapyridine Penicillin therapy was followed by a great improvement in the patient's general condition, in spite of the dose being insufficient to maintain a detectable concentration of penicillin continuously in the blood

CASE 3 —Labourer, aged 48, of poor physique Admitted May 2, 1941 Carbuncle 4 in across over left scapula for 5 days , now discharging , pus grew pure *Staph aureus* History of chronic bronchial and nasal catarrh for 4 months Left axillary adenitis Hb 106% , red cells 4,970,000 , white cells 23,000 Blood urea 31 mg per 100 c cm Urine normal

May 3 penicillin 200 mg hourly for 5 doses by injection into intravenous drip as in case 2 , then 100 mg hourly No reaction Antibacterial activity continuously maintained in blood May 7 carbuncle much improved , slight tenderness, only slight serous discharge Dose dropped to 100 mg 2 hourly and then 3 hourly May 10 carbuncle almost completely resolved , no axillary adenitis , bronchial and nasal catarrh cleared , 100 mg penicillin 6 hourly for 4 doses and then stopped May 11 Hb 90% , red cells 4,970,000 , white cells 15,800 Blood urea 37 mg per 100 c cm Urine normal Temperature, which had been swinging 97°–101° F now normal and remained so Local treatment had consisted in kaolin poultice for first 48 hours, sodium sulphate dressing for next 48 hours and subsequently dry dressing May 15 discharged Seen as outpatient on May 19 when skin over carbuncle almost normal and patient generally well , right ulnar neuritis which cleared quickly, possibly from splinting arm for several days during infusion

White counts —May 3, 23,000 (polymorphs 87%) , 5th, 16,400 , 6th, 15,200 , 7th, 7800 , 8th, 9200 , 9th, 19,200 , 10th, 19,800 , 11th, 15,800

In this case the supply of penicillin was sufficient to enable a detectable concentration of penicillin to be maintained continuously in the blood for the first 4 days There was no toxic effect from the larger dosage The result was a rapid resolution of the carbuncle without its discharging and without scar formation In addition the chronic nasal and bronchial catarrh were cleared The white count was temporarily depressed on the 4th and 5th days but rose again in spite of the drug being continued

CASE 4 —Boy, aged 4½ years Admitted May 13, 1941 Cavernous sinus thrombosis from septic spots on left eyelid and face following measles 5 weeks before Had received 30 g sulphapyridine in 14 days before admission Semicomatose, incontinent of urine and fæces Gross œdema both eyelids (fig 6a), especially left, with bilateral proptosis Complete bilateral external ophthalmoplegia and 2 dioptres of papillœdema , neck rigidity , bilateral Kernig's sign and extensor plantar responses Moist sounds both bases Liver edge two finger breadths below costal margin Blood culture sterile Lumbar puncture gave a faintly yellow cloudy fluid under high pressure (see table III)

May 13 intravenous infusion of citrate saline at 10 c cm an hour (rate maintained with slight variations for 9 days, the site of infusion being changed 4 times) Penicillin injected into infusion , dose 100 mg hourly for two doses, 50 mg hourly for four doses, then 25 mg hourly May 14 pus from incision made into left eyelid and swab from nose grew *Staph aureus* X ray opacity of left antrum, ethmo clear May 15 blood sample an hour after dose of penicill showed no antibacterial activity , dose increased to 50 m hourly General improvement May 16 obviously bette swelling of eyelids largely subsided Blood taken just befo injection showed trace of antibacterial activity May 1 general and local condition vastly improved (see fig 6b) bilateral 6th nerve palsy and extensor plantar respons remained Penicillin reduced to 50 mg 3 hourly Sma corneal ulcer left eye treated with penicillin 1 in 5000, whic caused no discomfort May 22 improvement maintaine patient talking and playing with toys Chest clinicall normal Slight pyrexia still thought to be due to pyrogen i penicillin or to reaction from thromboses in veins used fo injections (see fig 7) Penicillin stopped May 26 progres good Temperature normal General condition excellen Eye movements returning X ray of sinuses only sligl clouding left antrum , chest , patch of consolidation left ape and small ring shadow right mid zone These thought to b embolic signs but general condition so good that no furth penicillin needed May 27 1 A M vomited and had gener convulsions Lumbar puncture gave uniformly blood stainc fluid under high pressure Became comatose with nec rigidity, positive Kernig's sign and spastic limbs May 28 temperature began to rise again May 29 appearance muc as on admission Penicillin 2 g given in next 36 hours, bu died May 31

* Cell count done after fluid had stood for several hours

Autopsy (Dr A H T Robb Smith) —Brain showed n thrombosis of main venous sinuses , adhesions and ol hæmorrhage in hypophysial region Considerable old an recent hæmorrhage in region of pons and cerebellum due t rupture of aneurysm on left vertebral artery Cavernou sinus region and left orbit occupied by œdematous granulatio tissue , left carotid artery partially occluded by thrombus in its cavernous course and completely occluded in its bony course Both lungs showed scattered abscess cavities, larger ones being air containing cysts lined by yellowish membrane, smaller ones containing yellowish material not exactly resembling pus Other orgar not remarkable

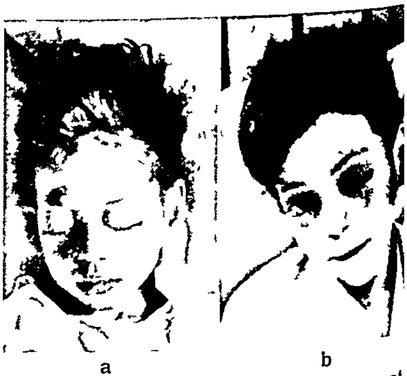

FIG 6—Case 4 (*a*) at beginning of treatment (*b*) on 11th day of treatment

Histologically granulation tissue is essentially simil whether in lung abscesses, orbital tissues or cavernous regior (fig 8) There is a small central area of necrosis sometim containing a few gram positive cocci , around this is a œdematous exudate with lipoid containing histiocytes surrounding this is a granulation tissue formed largely (histiocytes containing lipoid and blood pigment, lymph cytes and plasma cells with a very occasional neutroph

DRY AFTER-TREATMENT OF INFECTED HANDS

HAMILTON BAILEY, F R C S
SURGEON TO THE ROYAL NORTHERN HOSPITAL

To soak infected hands in hot baths and apply mentations " as hot as can be borne " are methods of eoperative and postoperative treatment which are so grained in the medical and nursing professions that it ll take time for them to be supplanted Let us review e disadvantages of the " wet " method —

(*a*) It is extremely painful I still remember dreading e time coming round for my own fomentations, which ere applied at two-hourly intervals by a conscientious ster who believed in fomentations being really hot

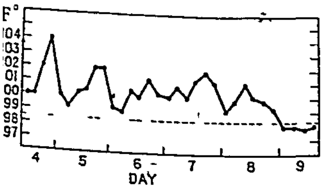
(*b*) General swelling and tenderness of the hand, due) the hot applications, mask localised swelling and enderness due to extension of the infected process, onsequently the accurate diagnosis of the location of us is often delayed

(*c*) The hot-water treatment produces scalding, which, i addition to causing pain, predisposes to superficial nflammation and even paronychia of uninfected digits[1]

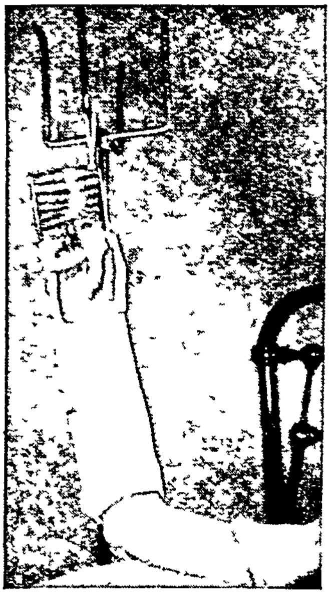
(*d*) Sodden, swollen tissues tend to narrow exits hrough which pus can escape

TECHNIQUE OF THE DRY METHOD

During the past three or four years I have been increasngly impressed by the manifold advantages of the dry ethod of treating seriously infected hands The best ay of expounding its principles will be to quote the case f a surgical staff-nurse with suppurative tenosynovitis f the index finger As I have suffered from suppurative enosynovitis myself, and as this patient was a trained bserver, it was possible to contrast and compare the vet and dry treatments with more than ordinary nlightenment



I was called to see the nurse four days after the symptoms nd signs had begun She had scratched the back of her ndex finger while doing a dressing, the facts that the original lesion was on the dorsum of the finger and that the patient could flex the finger without much pain had been the cause of diagnostic difficulty to several observers (How often the all-important diagnosis of suppurative tenosyno-itis is not made because a patient can flex the finger, it is far ore significant if the infected digit cannot be completely xtended by voluntary effort) By the time I saw this atient she was gravely ill She had received sulphonamide herapy and the usual baths and fomentations, but the temerature had continued to rise, and the toxic symptoms were o great that septicæmia was feared Her temperature was 04° F and pulse rate 140 By palpation with a burnt atch stalk the point of maximal tenderness could be defined learly over the flexor surface of the head of the second metacarpal Under Evipan anæsthesia the tendon sheath and the corresponding lumbrical space, both of which were found to be distended with pus, were drained, and a wisp of Vaseline gauze was tucked into the proximal end of the sheath A piece of Gamgee tissue was wrapped round the forearm, and a length of Cramer wire was bandaged firmly to the dorsal aspect of the forearm A suitable piece of Sorbo sponge was placed between the Cramer wire and the dorsum of the hand and fingers, and the incised index finger was encased in a Viscopaste bandage which did not fix it to the splint except at the base of the finger, where it was carried round the splint and the palm The sound fingers were bandaged lightly to the splint, in order to extend them The patient having been transferred to bed, the arm was elevated by suspending the end of the Cramer wire from an irrigator stand The nurses were instructed that if the patient was comfortable and the temperature falling the dressing should not be disturbed, neither should the position of the arm be altered for 48 hours On the third day she complained of aching in the shoulder, this was eased somewhat by adjusting the pillows, but she asked to have the arm lowered This was done, and the dressing was changed and the viscopaste bandage reapplied After about an hour the hand began to throb, and the patient was glad to have it elevated again, for in the raised position the pain and throbbing vanished The report on the pus was now to hand, it was a pure growth of *Staphylococcus aureus* Each day the flexed, uninfected fingers were bandaged back a little more to the Cramer wire, until they were extended completely The patient, whose general condition had improved greatly by the ninth day, was encouraged to move the fingers frequently under the turn of bandage



While this treatment is essentially dry, dryness is not a fetish About the fourth day the vaseline gauze drain is removed and the hand is put into an antiseptic bath for five minutes and washed If there are any sloughs the wound is irrigated, the hand is then dried and the splint reapplied Whether the vaseline gauze drain is replaced or not depends on circumstances, in this case it was removed, and the arm was kept elevated for 20 days For 1½ hours each day it was lowered, and during this period the bandage was undone and the patient performed finger exercises under infrared rays On the 21st day she was allowed up The wound had healed and movement of all the uninfected fingers and the thumb was perfect

In nearly all the cases in which I have employed dry after-treatment for seriously infected hands the infecting organism has been a streptococcus As sulphonamide therapy came into general use about the same time that I changed from the wet to the dry treatment, it might be argued that it was the sulphonamide which was playing the major part in the improved results I have no wish to detract from the great benefits which have accrued from sulphonamide therapy in this branch of surgery, but the case reported here demonstrates that, with adequate drainage, dry after-treatment and elevation are in themselves an advance, I think it unlikely that in this instance sulphonamide therapy played any part

In my experience, the dry after-treatment has proved uniformly satisfactory T B Mouat, whose experience is greater than mine, informs me that both he and Sister Wray, of Sheffield Royal Infirmary, find that in a small percentage of cases progress is unsatisfactory In such cases Sister Wray changes to what are known as " rotation " dressings for about 48 hours The hand remains immobilised, but every 4 hours the following moist dressings are applied in turn eusol, normal strength,

by night After 2 days little progress had been made and continuous application considered necessary Modification of Bunyan Stannard bag (Bunyan 1940) made to fit eye and 1/5000 solution penicillin run into it New bag applied each day, and remained full for about 8 hours, after which began to leak and needed refilling occasionally After one day of continuous application less injection of conjunctiva and patient free from pain for first time Treatment given for 4 days, on second day concentration of penicillin raised to 1/1000 but this caused slight irritation and for last 2 days solution of 1/2500 used By end of fourth day eye greatly improved, conjunctiva only slightly injected and corneal opacity almost disappeared, deeper ulcer remained, but considerably smaller Treatment continued with hourly drops of 1/2500 penicillin and after one day strength increased to 1/500 "therapeutic penicillin," which caused no discomfort June 9 (8 days after bath had first been applied) ulcer no longer stained with fluorescein, but still slight injection Treatment continued with drops of 1/500 penicillin, 2 hourly by day, 4 hourly by night, but further improvement slow June 20 patient discharged, ulcer healed, leaving only slight residual infiltration of conjunctiva, which had cleared a week later

CASE 8—Girl, aged 19 Burnt her face with cigarette end 6 weeks before admission, burn became infected and from this a septic rash spread over face Week before admission left eye became red, swollen and painful On admission on June 9, 1941, many small crusted impetigo like spots on both sides of face Left conjunctiva inflamed and showed thick mesh of fine vessels, cornea clear, lids slightly swollen Eye-bath as in case 7 applied and filled with 1/2500 penicillin Next day less injection and eye not painful After 3 days eye almost normal, treatment continued with drops of 1/500 penicillin 2 hourly by day and 4 hourly by night June 13 eye normal On and after June 10 ointment consisting of 1/500 penicillin in hydrated lanoline applied to rash on face twice daily When patient was discharged on June 15 rash had healed completely with only slight residual erythema

While the treatment of these 2 cases was in progress, some 1/2500 penicillin solution was given to 2 outpatients who were told to apply drops of the solution hourly by day

CASE 9—Man, aged 24 Foreign body in left eye May 28, 1941, developed acute conjunctivitis treated with boracic acid and zinc lotion, collosol argentum, and painting lids with silver nitrate Only slight improvement by June 7, when given penicillin drops, in next 2 days rapid improvement, with complete relief of pain Slight residual conjunctival infiltration, so treatment continued until June 19, when healing complete

CASE 10—Woman, aged 20 Developed acute muco purulent conjunctivitis on June 5, 1941, treated for 2 days with boracic acid and zinc lotion and by painting lids with silver nitrate Penicillin drops given on June 7, and 5 days later the eye was almost normal

In these 4 eye cases, 2 of which had proved resistant to routine therapeutic measures, penicillin application resulted in rapid relief from pain and resolution of the inflammation In none was there any ill effect

Discussion

From experiments in vivo and in vitro much evidence has now been assembled that penicillin combines to a striking degree two most desirable qualities of a chemotherapeutic agent—low toxicity to tissue cells and powerful bacteriostatic action Its capacity to prevent multiplication covers a wide range of bacterial species, including some of the most common and destructive organisms with which man may be infected, and this bacteriostatic action is in no way interfered with by body fluids or pus, and only to a limited extent by very large numbers of organisms

The crucial test, however, of the efficacy of any chemotherapeutic agent is whether it can favourably influence a natural infection In spite of the difficulties of large-scale production in the laboratory, we have collected enough material to try penicillin in a few cases Cases 1, 2, 4, 5 and 6 had previously been treated with various forms of chemotherapy and some also by surgery They were, in fact, patients for whom no further treatment likely to be of benefit could be proposed Case 3 had had no previous treatment In all patients the temperature fell and the general and local condition improved Where there was a recrudescence of infection it could in each case be attributed to insufficient administrati penicillin The only toxic effect of any importance seen was due to a pyrogenic impurity, which could removed, and it is worth noting that an impro in the spirits and appetite of the patient during was remarked on in all the cases Where local applicat has been tried, it has given equally promising results

Methods of administration and dosage have ne been tentative, but the many points which still investigation await an adequate supply of p Enough evidence, we consider, has now been to show that penicillin is a new and effective type chemotherapeutic agent, and possesses some properties known in any antibacterial substance hitherto described

Summary

A description is given of the cultural and other con ditions required for the effective production of penicilli by *Penicillium notatum*, and of methods of small scal mass production and assay of material suitable for thera peutic use in man

Observations on the absorption and excretion of th drug have been made on the rabbit, the cat and man The material is excreted in high concentration in the urine of all three species There is a high concentration in cats' and less in rabbits' bile (that of man has not yet been investigated)

Evidence is produced of the low toxicity of the sub-stance when applied directly to body tissues

No toxic effects attributable to "therapeutic peni-cillin" injected intravenously have so far been observed, though crude penicillin products contain a pyrogeni substance which can be removed by suitable treatment

It is shown that the growth in vitro of many pathogenic bacteria is prevented by purified penicillin at a dilution of one in a million or more, and that others possess diminish ing degrees of sensitiveness, some being quite resistant

Proof is given of the inability of blood, pus and tissue derivatives to prevent the action of penicillin

Adaptation of *Staph aureus* to high concentrations of the substance has been demonstrated, and this has been shown not to be due to the development of a penicillin destroying enzyme

A comparison is made between the antibacterial activity of penicillin and the sulphonamides, and reason are adduced why penicillin can be expected to operate when the sulphonamides are ineffective

During the course of some therapeutic trials in human infections it has proved possible to secure and maintain a bacteriostatic concentration of penicillin in the blood without causing any toxic symptoms After intravenou administration a large proportion of the active substance can be recovered from the urine and used again

Pencillin was given intravenously to five patients with staphylococcal and streptococcal infections and by mouth to one baby with a persistent staphylococcal urinary infection It was also applied locally to four cases of eye infection In all these cases a favourabl therapeutic response was obtained

The work was planned and started by E Chain and H W Florey The chemical and biochemical part of the work was carried out in the main by E Chain and E P Abraham N G Heatley devised the assay method and developed and supervised the production of penicillin M A Jennings and H W Florey have conducted the biological tests except those especially mentioned in the text A D Gardner has con ducted the bacteriological investigations and made some special observations on the growth of the mould C M Fletcher (of the Nuffield Department of Medicine) has been in charge of the administration to man The successful conduct of the work to its present stage has only been made possible by the closest collaboration of all concerned We wish to thank the physicians and surgeons who placed their cases at o disposal

We wish also to acknowledge the work of the followi technicians, without whose efforts adequate supplies o penicillin could not have been produced D Callow, P Callow, E Cooke, S A Cresswell, G Glister, C Inayat, J Ken M Lancaster, P McKegney, E Vincent

We are indebted to the Medical Research Council for a gran towards the expenses of large scale production, and to th Rockefeller Foundation for providing for technical assistanc and expenses

CARE FOR HOME GUARD CASUALTIES

THE collection evacuation and hospital treatment Home Guard casualties is the duty of the local R P authorities and of the hospitals of the Emer- ncy Medical Service They owe a similar duty wards civilian casualties, but whereas A R P nbulances will proceed right up to the spots at which vilians have been injured and will send out first-aid arties to collect those outside the reach of ambu- nces they are not allowed to extend these particular acilities to Home Guard casualties Their ambulances nd first-aid parties are forbidden to go further forward han casualty collecting posts which must be estab- ished by the Home Guard, and to which the Home Guard must carry their own casualties They must also be responsible for the care of these casualties until they are actually placed in ambulances These arrangements have made it necessary for Home Guard medical authorities to consider how long the arrival of ambulances may be delayed The air attack on Crete went on for several days and presumably—though there is no precise information—any urban hospitals there were out of action long before active invasion ceased One of the chief aims of parachute troops, or of other invaders from the air is to obtain motor transport and the ambulance offers ideal camouflage for an enemy A further difficulty to be anticipated is the breakdown, partial or complete of telephone services To get a wounded Home Guard removed by ambulance at least three telephone calls must be made from the place of wounding to the local control office, thence to the hospital to see what wounded can be accepted, and from the hospital to the ambulance centre with instructions for the journey In some circumstances ambulances might not be available for days rather than hours Some are prepared to write off the resulting death-roll and suffering as one of the incidental risks of war which cannot be avoided, but medical officers cannot accept this view as long as it is within their power to plan the care of H G casualties and incidentally of civilian wounded, who could hardly be excluded from H G posts when no other help was available

It is impossible to set up complicated posts like the first-aid posts of local authorities but, as Dr GORDON WARD has shown,[1] it is possible to arrange, on a voluntary basis, for protection from the weather, warmth, rest on beds, palliasses or cushions, simple cooking (soups and hot drinks), and such skilled care as may be possible (in many cases a doctor will be available, in others a trained nurse or V A D, in others simple home nursing) The Government provides for each post 52 pad and bandage dressings, 2 small tubes of tannic-acid jelly, 2 triangular bandages and a set of splints of which the longest measures 17½ in This supply is intended only for the most elementary first-aid treatment and was not intended for use during a period when ambulance traffic might be indefinitely suspended There are other sources from which further supplies may be obtained—from doctors' surgeries, chemists' shops and private houses where the supplies are much larger than is generally appreciated, and from the Red Cross societies From these each county could equip enough casualty collecting posts for its needs Mr A L ABEL tells us on another page that in his area the difficulty has been completely overcome through the generosity of the Canadian Red Cross, but in general the H G medical officer can only tap these supplies if he first collects funds, and this is a duty which may well fall to his lot Supplies are also being held in reserve by military and E M S hospitals and a portion of this stock might be dispersed among casualty collecting posts, where it would be ready for an immediate emergency rather than concentrated in vulnerable centres Official authority would have to be given by the Minister of Health before this could be done

The number of posts to be established must be decided The officially recognised plan is to site such posts within reasonable distance of strong points which may be held by the Home Guard The difficulty is that such posts are necessarily static and cannot be moved about if a Home Guard unit proceeds from one position to another The alternative is to dot the posts about the country or town in such a way that wherever a Home Guard may be wounded he will find assistance within the distance *it is practicable to convey him by stretcher* To carry a man on a stretcher as much as a mile is a serious task but it is scarcely possible to fix up the posts closer than this Even if every sort of hospital and civilian aid-post is counted as an already established casualty collecting post many more will have to be set up before such a network is established' but the task has already been accomplished in at least one county

PENICILLIN IN ACTION

SINCE it was first described by FLEMING in 1929 penicillin, an active principle of the mould *Penicillium notatum*, has been used in some bacteriological laboratories for the isolation of Pfeiffer's bacillus and *Bacillus pertussis* because of its rather selective bacteriostatic action on gram-positive organisms Last year a stable product, obtainable in liquid or powder form was shown by a team of workers[1] in the department of pathology at Oxford to have high claims as a chemotherapeutic agent if only it could be produced in quantity The Oxford workers have now shown that large-scale production and purification is a practical possibility By a fine piece of concerted work they have prepared a substance which seems to have unique properties even in an age which will go down in history as the second chemotherapeutic era, although neither in their first nor present report is there any clue to the chemical formula of penicillin

The optimum conditions—temperature, gaseous environment, pH, substrate, adjuvant and inhibitory factors—for a good yield of penicillin were first determined Once the surface felt of the mould was well formed over a shallow layer of fluid medium, several batches of penicillin could be prepared by withdrawing the underlying fluid and adding fresh medium, but strict sterility was essential because penicillin is destroyed by certain bacteria It is also destroyed hydrogen peroxide, 10%, magnesium sulphate, 5%, normal saline Dry treatment is then recommenced

I would still be following the traditional path of baths and fomentations in these cases were it not for the stimulus of my friends Mr Robert Kennon, who exhorted me to stop scalding infected hands, Dr A Tudor Hart, who asked me to try elevation, and Mr T B Mouat,[2] who allowed me to draw on his great experience and knowledge of the literature

PLASMA UTILISATION IN SERUM PROCESSING

L E R PICKEN, Ph D Camb
LATELY BALFOUR STUDENT IN THE UNIVERSITY OF CAMBRIDGE
(*Regional Blood-Transfusion Laboratory, Cambridge*)

IN transfusion laboratories where serum is filtered, and in regions where citrated rather than defibrinated blood[3] is used for whole-blood transfusions, the relatively small volume of citrated plasma accruing from the blood bank, if not wasted, has either to be stored unfiltered or filtered separately This note describes a simple method by which plasma from "time-expired" citrated blood can be processed with serum, thus avoiding waste and saving time and labour in the filtration process

The method is based on the fact that fresh serum clots citrated plasma, and consists essentially in the conversion of plasma into serum by means of a "natural" coagulant—serum itself Into the types of clot formed and the time relations of their formation over the whole range of mixtures of serum and plasma studied it is not proposed to enter here Of practical importance was the observation that the fibrin gel formed in mixtures of serum and plasma in certain proportions, while exhibiting but slight spontaneous contraction at room temperature, can be reduced to a compact fibrillar mass by shaking vigorously for a few minutes This is possible even in gels which have remained undisturbed for several months

In fixing the proportion of serum to plasma to be adopted for routine plasma utilisation, the end sought has been the conversion of fibrinogen into fibrin as completely and rapidly as possible by the addition of the smallest possible volume of serum It has been found that the fibrinogen of relatively fresh plasma—that is, plasma separated from citrated whole blood (120 c cm of 2 5% sodium citrate to 420 c cm of blood) from 7 to 10 days old—can be converted into fibrin by mixing one part of plasma with five parts of serum If 80 oz screw-capped Winchesters are used, convenient volumes are 1500 c cm serum and 300 c cm plasma With a larger total volume and hence a smaller air-space the mechanical disturbance produced by shaking is inadequate for good contraction of the gel The serum used is separated from clotted blood in the manner described by Harrison and myself[4] and is not more than 6 days old from the time of bleeding Its clotting powers diminish slowly with age and are appreciably reduced by filtration The fluids are withdrawn from their respective pooling bottles (recently taken from the refrigerator at a temperature of 2–4° C) and mixed, under strictly aseptic conditions The mixture is allowed to stand for 24 hours at room temperature, or may be warmed to 37° C and kept at this temperature for 2 hours Each Winchester is then shaken vigorously for 1 or 2 minutes and returned to the refrigerator for a day or so Before filtration the greater part of the fluid is strained, without further manipulation, through a funnel lined with several thicknesses of gauze to remove small clots Any large fragments of the gel passing into the funnel can be induced to contract by stirring with a glass rod If now the Winchester is shaken briskly the remainder of the gel contracts still further, and the rest of the serum can be strained off The serum is now ready for filtration On 1800 c cm of the mixture the loss entailed by this method of plasma utilisation is 5–10 c cm

Provided the volume of plasma from time-expired citrated blood in hand does not exceed a fifth of the volume of serum to be separated, it can be clotted in the way described here and processed as serum This does not involve any delay in processing, since it is unnecessary to wait for all the corpuscles to settle before using the serum to clot plasma The few corpuscles remaining in suspension after the separated serum has stood for days at 2–4° C are removed in the contracting fibrin network

If it is not essential that fibrinogen should be rapidly converted into fibrin, a much smaller proportion of serum may be used Thus at room temperature the fibrinogen of samples of plasma mixed with a fifth of the volume of serum is completely converted into fibrin in 3 months At the end of this period, provided the mixture is sterile, it can be filtered and stored as dilute serum

The times and quantities given here have been worked out for serum separated in one particular way[4] Since such factors as degree of hæmolysis[5] and age influence the clotting powers of serum, it will be necessary to determine by experiment what proportion of serum to plasma to adopt under any given set of working conditions In assessing the completeness of fibrin precipitation in the mixture, it is important to note that a concentration of fibrinogen too small to be detected by heating at 56° C may in time give rise to a precipitate of fibrin The filtered product is stored at room temperature for a month before issue If a precipitate does not form within a month of the date of filtration the bottles can safely be issued If a precipitate should form, the bottles affected are allowed to stand for a further week or so until precipitation has ceased, and are then refiltered

Reviews of Books

Science and Seizures

New Light on Epilepsy and Migraine By WILLIAM G LENNOX, M D, Sc D, assistant professor of neurology, Harvard University, visiting neurologist, Boston City Hospital London Harper and Brothers $2 Pp 258

IN this simple little book Dr Lennox has set out the modern conception of the convulsive states, in the broadest sense, for the benefit of the intelligent and interested layman The book is far too elementary for the well-informed practitioner, who would have to pick his way through many popular similes and naively expressed generalisations to reach a synopsis of recent knowledge or rational treatment It has been written for the public who have a personal or philanthropic interest in epilepsy and migraine, in an attempt to throw aside the veils of superstition and ignorance which shut off epilepsy from other equally respectable organic diseases This public is less dynamic in England than in the United States where they have formed themselves into a "Laymen's League against Epilepsy," which is largely responsible for the present publication Dr Lennox has done well to express his vast knowledge of epilepsy, much of it gained by his own research, in such simple and short chapters That he has perhaps over-emphasised the electroencephalographic aspect of epilepsy is shown by the bibliography Despite this, many practitioners will be glad to know that such a simple exposition is available for their epileptic patients or families

Textbook of Clinical Pathology

(2nd ed) By ROY R KRACKE and FRANCIS P PARKE Emory University, Georgia London Bailliere Tind and Cox Pp 780 33*s*

THIS edition has been thoroughly revised by fourteen contributors and includes a chapter on t determination of vitamins and hormones, methods f estimating amylase in blood, and sulphanilamide, sulph pyridine and sulphathiazole in blood and urin absorption tests for infective mononucleosis, vitamin with determination of prothrombin, in blood, and chapter on the diagnosis of venereal lesions T authors explain in the preface that the book is design primarily "for accurate and comprehensive teaching this important subject to students of medicine, and t interpretation of laboratory findings for the practition of medicine" A wide field is covered, including hæmat logy, biochemistry, immunology and bacteriology T reader will find the descriptions of methods detailed a the photographs and diagrams useful of opinion in this country to the effect that in the run it would prove to be a major economy to ect all Army recruits to miniature radiography, a view to keeping sufferers from tuberculosis out of Army It may be that Lord HORDER's committee right in deciding that mass radiography is at ent impossible for the Army, though some records apidly developing invalidity among soldiers give se for anxiety on that score There can be no ibt whatever that in these times of increasing erculosis prevalence and risk it is essential to make mediately available for known cases such measures have been proved to be of value in influencing ourably the clinical course of the disease and in ntrolling its infectivity There are not available roughout the country sufficient beds for the treatent of cases of tuberculosis that urgently require natorium care Some of these beds were diverted the early stages of the war to casualty reception hough this state of affairs has now been largely ectified), but surely there can be no excuse in these ays for leaving infective cases under bad home conditions, where spread is almost inevitable and where here is no prospect of securing for the patient that pecialised care which is so important from every point of view Difficulty has been experienced in securing sanatorium treatment for patients boarded out of the Army Too often these patients have to be allowed to return to their homes in an infective condition, sometimes after many weeks of waiting have failed to secure for them the necessary sanatorium accommodation With the improved results obtainable from modern methods of treatment the need for anatorium provision for these cases is greater than ver such treatment is, indeed, an absolute necessity f one very obvious method of influencing the incidence f tuberculosis in time of war is not to be neglected

CANCER AND ULTRAVIOLET LIGHT

DURING the past twenty years two lines of work ave chiefly engaged the attention of those interested n experimental cancer research On the one hand he production of cancer by means of pure chemicals as shown that neoplasms may be produced by substances closely related to and in some cases identical with compounds formed by the bodily metabolism On the other hand certain viruses have been found to be closely related to the genesis of malignant tumours Less attention has been given to physical means of producing cancer, although in addition to radium and X rays it is now known that ultraviolet light is carcinogenic Ever since Unna[1] described, under the name of *Seemanshaut*, certain precancerous changes in the skin of sailors, it has been realised that wherever, as in Australia, the southern United States or the Argentine, people of European extraction live in a semitropical environment an excessive amount of cancer of the skin of the face and hands results The incidence in such countries s always greatest among farmers and others who are most exposed to the weather, while the minimum time of exposure necessary to ensure the development f cancer is in the neighbourhood of fifteen years

Nothing was known of the exact cause of this high susceptibility to skin cancer except that it was due to xposure to wind and weather In 1928 however, indlay[2, 3] showed that exposure of mice to a mercury-*vapour lamp was capable of producing* cancer on the backs and ears of the mice the effects not being due to the heat but to the light emitted by the lamp Subsequently Findlay[4] produced skin papillomata in the rat, the time necessary for the appearance of the tumours being longer than in the mice These results were confirmed both in rats[5] and mice [6] Later Huldschinsky[7] produced sarcoma in the corneas of rats by prolonged exposure to ultraviolet light, while Roffo[8] found that exposure of rats to direct sunlight also caused carcinomata and sarcomata These results were also confirmed [9] More recent experiments have revealed the part of the spectrum which is actively carcinogenic Roffo[10] concluded that the active portion lay between 2900 and 3500A, although his experiments did not exclude wave-lengths below 2900A More definite results have been obtained by Rusch Kline and Baumann,[11] who found that carcinogenic action lay in the wave-lengths between 2900 and 3341A , wave-lengths of 2537 and 3341A and above were non-carcinogenic The carcinogenic wave lengths thus coincide in part with those most potent in the production of erythema although 2537A causes erythema without inducing tumours Little radiant energy is needed to initiate the changes which culminate in tumour formation 63 to 84 × 10^7 ergs per sq cm of effective mid-ultraviolet ' radiation being adequate when given over a period of three months The effect of certain conditions on the rapidity of development of ultraviolet light cancer has also been studied Findlay[2] found that cancer development in tarred mice was accelerated by coincident exposure to ultraviolet light, Bungeler[12] reporting a similar effect due to sunlight

Kohn-Speyer,[13] it is true, failed to find any synergic action between tar painting and exposure to ultraviolet light but since she failed to produce tumours with ultraviolet light alone her experimental conditions were unsatisfactory Taussig, Cooper and Seebig [14] however, found that ultraviolet light did not stimulate cancer production in mice painted with benzpyrene an effect which Dobriner and Mottram[15] regard as probably due to the extensive dermatitis set up by the combined action of benzpyrene painting and ultraviolet light Rusch and his colleagues[16] likewise found that 1 2 5 6 dibenzanthracene added to ultraviolet light did not accelerate cancer production on the other hand local applications of mineral oil did cause an acceleration of ultraviolet light carcinogenesis , cotton-seed oil, olive oil and wheat-germ oil caused slight acceleration while linseed oil retarded development Cholesterol in oil caused much acceleration when locally applied but when fed to mice exposed to ultraviolet light both Wahlgren[17] and Baumann and Rusch[18] found no acceleration of carcinogenesis though a high fat diet increased the rate of production of tumours These results are interesting in view of the theories which Roffo[19] has put forward in a long series of papers He believes that when skin is exposed to light the cholesterol content of the skin is increased and that cholesterol, or some derivative of it induced by exposure to ultraviolet light, is responsible for the production of carcinomata So far as the increased cholesterol content of skin exposed to ultraviolet light is concerned experiments show that it is true of the rat but not of the mouse or guineapig In view of the by exposure to highly acid or alkaline reactions, and occasionally, for no obvious reason little or no penicillin was obtained from a particular batch From the crude penicillin containing fluid, the active principle was extracted in an organic solvent—amyl acetate was used—from which the penicillin was re-extracted by shaking with phosphate-buffer or water at a pH of 6–7 Evidence of the presence of a pyrogenic substance at this stage meant treatment with charcoal, re-extraction with ether, absorption by alumina, and further extractions until an aqueous solution—the non-pyrogenic or therapeutic penicillin—was obtained as a deep reddish-orange fluid This substance saturated with ether, is stable, and can be stored as such in the refrigerator, or dried and left in the desiccator since the powder is hygroscopic For dispensing, the ether-containing solution would be used after removal of the ether by suction The whole process is complicated and would have to be carried out with great care but large scale production should be well within the compass of a biological institute engaged in the preparation of bacterial toxins and antisera About 100 litres of medium are required to produce 1 g of therapeutic penicillin, which represents about a third of the total substance in the crude liquid Obviously penicillin cannot yet be easily produced on a large scale like the sulphonamides, or at a cost which would allow it to be freely used, even though the dosage for generalised infections is no more than 1 g per day As with other biological products, a stable standard and a reliable method of assay are required, the Oxford workers' method is to test the bacteriostatic activity of penicillin by adding the fluid to an open cylindrical tube set in a plate of agar-medium seeded with *Staphylococcus aureus*, and measure the diameter of the inhibitory zone after incubation This technique is also used for determining the presence of penicillin in the blood or urine of treated patients

In-vitro tests of the bacteriostatic activity of penicillin on a wide variety of bacterial pathogens brought out two remarkable features—(1) its selective action on certain gram-positive organisms, so that the amazingly low concentration of 1 in 1–2-million could prevent growth of the staphylococcus, *Streptococcus pyogenes*, and the anthrax and Welch bacilli, and (2) the lack of any interference with its bacteriostatic action by pus, serum or protein autolysates In this latter property penicillin has a great advantage over sulphonamides, as it also has power to inhibit the growth of relatively large inocula of organisms in any nutrient medium Thus, penicillin should act beneficially in heavily infected wounds and where there is much purulent discharge Because it is bacteriostatic and not bactericidal—thus resembling the sulphonamides but differing from gramacidin—penicillin requires the active help of phagocytic cells in dealing with an infective process It was therefore essential to find out if it had any toxic effect on leucocytes or other tissue cells Tests carried out with great thoroughness showed that penicillin was devoid of toxic action on living cells and delicate tissues in concentrations of 1 in 500–1000, which is considerably greater than the effective therapeutic strength Here again penicillin proved superior to the sulphonamides and to proflavine, which is probably the least toxic of the useful antiseptics For therapeutic use in systemic infections an immediate difficulty was the susceptibility of penicillin to acid, so that administration by seemed to be ruled out if a high concentration in tissues was desired Absorption from the int the cat and of man (given by stomach tube) moderately good, and means of avoiding destruct of the active principle by gastric juice can no do be devised In one of the Oxford cases a bac concentration was in fact maintained in a child's by giving the penicillin by mouth with bicarbonate Given intravenously to man, an injecti of 200 mg produced no obvious toxic effect blood samples still had slight bacteriostatic action aft 2 hours and urinary excretion continued for at lea 6 hours Half or more of the total dosage given to two patients was excreted in the urine and part of th substance was recovered for future use.

Unless chemical synthesis becomes possible, th difficulties and cost of production of penicillin will probably limit supplies If so its use should be largely confined to infections not likely to benefit from sul phonamide therapy Chief among these are infection with local thrombus-formation and metastatic lesion, such as acute and subacute staphylococcal pyæmia, bacterial endocarditis and the septic thrombophlebitis produced by anaerobic streptococci and *Bacterium necrophorum* The efficiency of a chemotherapeutic agent in these infections depends not only on its potency against the infecting organism but also on its diffusibility into infected and dead tissue Experiments to test this property should be carried out with penicillin as HAWKING[2] has recently done with the sulphonamides, meanwhile the post mortem findings in a case of staphylococcal pyæmia with cavernous-sinus thrombosis suggest that penicillin has this power of diffusion A substance that can produce so remarkable an amelioration of symptom in three classical cases of acute staphylococcal pyæmia must be ranked high among chemotherapeutic drug, for despite the claims on behalf of sulphathiazole, staphylococcal antitoxin and bacteriophage, there i as yet no sovereign remedy for generalised staph coccal infection The excretion of penicillin in c bile may be an indication for trying its effect typhoid fever and typhoid carriers In their liminary report, the Oxford workers described benefit obtained in animals infected with staph coccus, streptococcus and *Clostridium septi* it seems a promising step to extend this of the investigation to animal infections which si late the sulphonamide-refractory infections of ma

THE THREAT OF TUBERCULOSIS

EXPERIENCE shows that war-time conditions fav an increase in the incidence of tuberculosis D A HART's figures demonstrated such a rise during period 1914–18, and it has recently been elicite reply to Parliamentary questions that already trend of tuberculosis incidence has again tu upwards Doubtless many factors contribute increased tuberculosis prevalence in time of war, it may be that some of the responsible factors unavoidable It is not easy to influence the str that necessarily emerge from the complex tissu war environment, and it becomes increasi important on that account to control so far as pos the factor of infectivity There is still a consider

URKING-PLACE OF THE HEAD LOUSE

CUATION revealed that large numbers of received n were lousy This led to much acrimonious sion between officers of evacuating and receiving nties and to a piece of research work,[1] fostered by inistry of Health and the Board of Education, contradicts the experience of thirty years' school al practice Kenneth Mellanby approached the ment of lousiness from a new direction He used ecords made of new admissions to 32 English tals, and he suggests that since each hospital patient pected on several occasions these records are likely e more accurate than figures drawn from school inations made hurriedly and at infrequent intervals e says, the hospital nurse becomes highly expert in ting vermin, and their detection and removal is ed on as of great importance in a hospital His stigation included 7 large cities, 5 smaller county ughs, 2 other boroughs and rural areas in 6 counties, ging in a total of 60,000 observations In some ntals a division is made between live lice and nits, Mellanby does not consider this worth making The ntals covered were mostly fever hospitals, and this hted the sample slightly but not seriously in the ction of poorer and younger patients The main ings were as follows —

Age (years)	TEN INDUSTRIAL CITIES		FOUR RURAL COUNTIES *	
	Infested (%)		Infested (%)	
	Male	Female	Male	Female
Under 1	11	12	0	0
1	36	39	8	8
2– 4	42	50	8	5
5– 8	33	50	5	9
9–13	27	50	4	6
14–18	12	27	0	6
19–30	1	9	0	0
31–70	1	8	0	0
70 upwards	1	6	0	0

These figures are taken from Mellanby's graph and are oximate only

the evacuating cities, Birmingham was second to don in the amount of censure it received for sending y children into the reception areas, so it is not rising that Dr H P Newsholme, who with justice roud of his welfare services, took up the challenge of official research in opening a discussion at the ference of public health nurses at Birmingham on e 21 Dr Newsholme makes the rates of lousiness nfants less than 1%, in preschool children 3 5%, and chool children 11 8% These smaller figures are not removed from those found by most child-welfare and ol medical officers at the outbreak of war, and Dr sholme is clearly satisfied that they give a fairer ure than Mellanby's hospital records However may be, on reception the lousiness of the received dren was considerably greater than that of the resident dren The difference was, no doubt, exaggerated in many reception areas no consideration was given what should have been expected Tempers were t at the time and some sharp things were said, but the uee children who remained in the country were soon factorily cleansed Mellanby thinks the difference een town and country mainly arises from a difference utlook—parents in the country consider it a disgrace heir children to be verminous, whereas town parents k less of it He urges more thorough examination hool-children, with efforts to educate both children parents in cleanliness By unremitting labour it ld be possible to reduce the infestation-rate of school-tren in school term to 10% everywhere, to 5% in y areas and to zero in a few schools in specially ured districts Relapse is invariable if, or when, control is slackened, for we are unable to attack the main reservoirs now remaining—a few hopeless families and the heads of girls who have left school The Board of Education and the Ministry of Health are reluctant to take efficient action, for it would be both unpleasant and unpopular But the reservoirs have got to be tackled seriously some day It has been suggested that the present fashion of hair dressing favours lousiness in young women, because they like to leave their waves and curls undisturbed Lousiness is certainly widespread in girls seeking employment after leaving school, though judging from the few districts where reliable information is obtainable it is less than it was In districts where employers will not take girls unless their heads are scrupulously clean the amount of lousiness in the population is low In most districts and most industries little attention is paid to heads, and a nurse at the Birmingham meeting reported that of 58 people found infested by a works doctor 28 preferred to give notice rather than go to a cleansing station Nevertheless, tobacco and sweet factories have demonstrated that the difficulties can be overcome

SIDEROCYTES AND THE IRON CYCLE

IN a letter last week appealing for blood-films from human embryos or premature babies, H Grüneberg reported finding red blood-cells in which "free" iron could be detected by the Prussian Blue test—he called them "siderocytes"[1] They occurred in newborn mice of a special variety having a recessive gene for 'flexed-tail and belly-spot"—a condition associated with a severe but temporary anæmia, siderocytes were also found in small numbers among the red cells of normal newborn mice and rats during the first week of life Does this free iron of the siderocyte represent a portion of the original iron ration of the cell that has failed to be combined in hæmoglobin, or is it a product of premature breakdown of hæmoglobin? Even though this may be a peculiarity of rats and mice only, it is interesting because it raises the question of the source and fate of iron in the red blood-cell, a subject reviewed by Schultze[2] Hæmoglobin is formed in the early nucleated stages of the red blood-cells which in the adult are found only in the bone-marrow, for its synthesis iron, protoporphyrin and globin are provided The protoporphyrin is a cyclical compound of four pyrrol rings which can be detected in immature red cells and is thought by Watson to be the substance producing the reticulocyte appearance with brilliant cresyl blue It is not certain whether protoporphyrin combines with iron to form protohæmatin which reduced to protohæm unites with globin to form hæmoglobin, or whether a protoporphyrin-globin compound is first formed which then incorporates ferrous iron to give hæmoglobin, in either case once the iron becomes attached to the protoporphyrin molecule it is no longer "free" The site of this process is probably the bone-marrow because mature erythrocytes cannot in vitro be made to take up iron, the process is rapid since experiments with radioactive iron have shown that it is only a matter of hours before ingested iron appears in the red cells in the blood When the erythrocyte wears out, the hæmoglobin is liberated into the plasma and is broken down, but the path is different from that of synthesis The final product is bilirubin, but if hæmatin is injected intravenously a corresponding amount of bilirubin is not formed, whereas it is formed if hæmoglobin is injected Apparently the scission of the porphyrin nucleus occurs while it is still attached to the globin, one of the connecting -CH- groups is oxidised and the porphyrin ring is broken giving a formula which can be represented as a straight chain of four pyrrol rings The globin and the iron split off leaving biliverdin which finally changes into bilirubin The iron—free once more—is released known carcinogenic action of certain sterols further work is required to determine whether carcinogenic substances are produced by the action of ultraviolet light on naturally occurring sterols Certain other experimental lines of investigation are also suggested by the cancer-producing action of ultraviolet light Ultraviolet light, together with X rays and radium, both of which are carcinogenic, is one of the most commonly used methods of inducing mutations in the chromosomes of the germ cells Recently Mackenzie and Muller[20] have shown that the wave-lengths producing such mutations in drosophila lie between 3000 and 3200A and do not appear to injure the chromosomes Does ultraviolet light function in a similar manner in inducing skin cancer or is it necessary to confine the term mutation to hereditary changes confined to the chromosomes ? In viruses such as those of tobacco mosaic, yellow fever and the rabbit fibroma hereditary variations in every way analogous to true mutations have been described, although at the level of organisation of the viruses chromosomes are unknown (cf Findlay[21]) In the case of the tobacco mosaic virus, Stanley[22] has shown that different strains of the virus protein differ in their chemical properties, while Knight and Stanley[23] have recently obtained definite information concerning some of the structural differences that exist between variant strains of the tobacco mosaic virus It is therefore not too much to hope that before long it will be possible to produce a true mutation by chemical manipulation of the tobacco mosaic virus molecule Finally, ultraviolet light cancer suggests a third possibility Is the action of ultraviolet light on the skin merely one of bringing to light and localising an "indigenous" virus ? Lambeau,[24] for instance, has shown that a latent zoster virus may be activated and localised by treatment with ultraviolet light Suggestive evidence of an "indigenous" cancer virus has lately been brought forward by Bittner[25] who has found that a "factor" present in spontaneous mouse cancer, as well as in mouse spleen and milk, can be frozen and dried When fed to mice of a low cancer-producing strain the incidence of mammary cancer is greatly reduced There is much to be done, as a modern poet has said, in "the gradual exploring of all the octaves of radiation"

THE death is announced on Aug 10 of SIR ALFRED RICE-OXLEY, late physician in ordinary to Princess Beatrice and medical director of the Princess Beatrice Hospital for Officers He was 85

Annotations

SURGICAL IMPORTANCE OF PLASMA PROT

THE extraordinary slowness with which p follows knowledge in medicine is nowhere more e than in the study of the body proteins In a discussing the replacement of plasma protein lo t burns, Elman[1] points out that dehydration and h concentration in severe burns had already been rec nised in 1855 by Buhl, and in 1881 Tappeiner had suggested the transfusion of serous fluid for the treatme of these cases Our knowledge of the functions of th plasma proteins in maintaining the fluid in the vesse was given a scientific basis by Starling in 1896 Now, after nearly 100 years of haphazard research, mo th uncoordinated, we have at last reached an era where the body proteins are receiving some recognition, surely a powerful argument for some responsible body to correlate, verify and pass into practice as rapidly as possible the results of individual researches Judging by the va t literature which has accumulated on the subject durin the last few years, much energy, time and paper would have been saved by such coordination The work done from the surgical aspect has been excellently summari ed by Ravdin,[2] who discusses the various effects of hypo proteinæmia This condition alone can slow down intestinal movements and delay the emptying of the stomach After intestinal operations, the tendency to œdema all over the body consequent on the reduction of plasma protein becomes intensified at the site of opera tion, causing swelling at the suture line even to the extent of physical obstruction of the bowel Further, the actual healing of wounds depends on adequate protein reserve, for a lowered plasma protein prevents normal fibroblastic proliferation, thus causing sutured tissues to fall apart when the stitches are absorbed—an accident w known to all abdominal surgeons The effect carbohydrate feeding in preventing damage to the li due to some anæsthetics is possibly due to the prote sparing action of carbohydrate, and liver protect could as well be brought about by adequate prot feeding The pernicious practice of starving patie before (and after) operations must, in the light of t knowledge, have been the cause of much unneces mortality and morbidity A rather more subtle po emerges If, as Ravdin points out, it is possible damage the liver by protein starvation, and if, as see likely, the liver is chiefly concerned with prot metabolism and regeneration,[3] might not a vicious cy be started by the initial protein depletion ? And what extent may this cycle be broken by plas transfusion ? It is clear that some rapid and accur method suitable for universal use is required for estimation of the plasma-protein percentage and amount of the total circulating protein The latter is more important because in the presence of uncorrec anhydræmia (as in burns) the plasma protein percent may be normal though the total plasma protein may greatly reduced along with the reduction of plas volume

One danger remains to be remembered during intravenous infusion of plasma The method present much used for the production of plasma by citrate method causes a serious dilution of the plasma the citrate solution, with the result that the final conc tration of protein may be halved This citrated plas if run too quickly into a vein, may cause pulmon œdema If the danger of reactions can be remo from serum, this substance, which is undiluted, shoul preferred

FERENTIAL DIAGNOSIS OF LUNG INJURIES

DISCUSSION AT PORTON

a conference held lately at the Experimental at Porton Sir JOSEPH BARCROFT who was in the uggested that a town might be attacked in a r of different ways at the same time A mixed casualties might occur, some gas (more perhaps ney guessed) some blast and so on The question om the point of view of the lung how to sort out the ties which might be due to the various causes He be- that nothing of this sort had been attempted before

ACTION OF POISON GAS

f G R CAMERON divided gases into those absorbed gh the lungs with little local effects and those which holly or mainly on the lungs producing bronchial ge and bronchopneumonia or alveolar damage and pulmonary œdema Arsine is an example of the group, particulates, chlorine hydrogen selenide, gene, nitrous fumes, mustard gas and lewisite ur belong to the second Bronchial damage results ronchial spasm and destruction of bronchial epithe- It may be caused either by the irritant gas acting he lining epithelium with liberation of histamine-like tances, or through irritation of nerve-endings ous glands are stimulated, with often a considerable pouring of mucus which tends to plug the bronchial ities and cause collapse Bronchopneumonia may ow such blockage when infection occurs Four views ve been held concerning pulmonary œdema

1 The gas may act directly on the alveolar capillaries, ering their permeability so that plasma exudes out into the spaces

The gas may liberate H substances from damaged lining olar cells

Œdema may be secondary to cardiac failure

Lung lymphatics may become blocked, with lymph stasis overflow into the alveoli.

le gases act on the capillaries—e g lewisite and tard Although there is little histological evidence phosgene alters permeability of capillaries, there is y reason to believe this to be the case The second is debatable since much uncertainty exists as to the ure of the alveolar lining Cardiac failure is most n a secondary feature of œdema and not the direct se No information exists about lymphatic blockage, ed, the function of lymphatics in the lung is obscure ain risks arise from these lung changes Bronchial m resulting from high concentrations of gas may to acute asphyxia and interstitial emphysema nchial destruction is more important because of the ger of bronchopneumonia or bronchiectasis, but mately these complications are not common monary œdema if acute may lead to cyanosis and th from asphyxia If not so acute, there is incapaci- on and liability to cardiac failure or infection of the Hæmoconcentration may also add considerably to risks of circulatory failure In the dog exposed to gene, hæmoconcentration is well marked, but it kly passes off Nevertheless, the œdema persists the animal may die days after from pure pulmonary ma In rabbits hæmoconcentration is rarely seen phosgene though œdema is well marked What efore is the significance of hæmoconcentration t significance, too, is to be attached to mild pulmonary ma? How quickly is œdema fluid absorbed from ? How much œdema is necessary to produce pacitation of the patient? These questions, which are eat practical importance still remain to be answered

EFFECTS OF HIGH EXPLOSIVES

of GEOFFREY HADFIELD confined his remarks to aid casualties presenting severe respiratory symptoms out obvious surgical injury Such cases included those suffering from "pulmonary concussion" with- damage to the thoracic cage, (2) those suffering asphyxia, and (3) those whose symptoms are the lt of pulmonary fat-embolism Pulmonary concus- is characterised by multiple pulmonary hæmorrhages of considerable size throughout both lungs, usually deep in the lung substance but with no constant relation to the ribs or ramifications of the bronchial tree Rib-markings can be identified only in lungs from infants or young children, suggesting that the elasticity of the thorax predisposes to their production Naked-eye laceration of the lung or irregular tracking of blood through the lung substance are exceptional, and often no blood is present in the pleural cavities The size of the hæmorrhage is clearly related to the survival period, reaching a maximum in about 4 hours In cases surviving for 36–48 hours, hæmorrhagic areas are on the whole no larger than in those surviving 4–8 hours only Capillary bleeding seems to be responsible for the hæmorrhage A fibrin network forms in the alveoli and a mononuclear cell exudate appears, so that in 36–48 hours the histological picture is strikingly reminiscent of lobar pneumonia in the red hepatisation stage ('pseudo-pneumonia") Asphyxia may be presumed to have been a major cause of death when the air-passages are found to be obstructed by powdered plaster brick dust, &c It may also be the cause of death when the thorax has been compressed by a heavy mass of wood stone or metal Inhalation asphyxial lungs often show hæmorrhages, other cases show collapse and œdema which is often much better marked in one lung than the other with the usual post-mortem signs of asphyxia Carbon-monoxide poisoning probably the result of bursting of gas mains, is a frequent complication of pulmonary concussion and asphyxia The proportion of cases in which fat-embolism can be deemed to have caused death is uncertain Small quantities of fat in the pulmonary capillaries are found in a high percentage of deaths from trauma of any kind Only when the quantity of fat is large and there is embolism of the glomerular capillaries can much importance be attached to this condition There is usually a latent period between the incident and the development of dyspnœa A gross traumatic lesion of subcutaneous fat with a collection of autolysing fat and blood-clot is usually found at autopsy Professor Hadfield then outlined the clinical manifestations of pulmonary concussion, emphasising the rapid development of shock with a quick, thready pulse accompanied by severe expiratory dyspnœa Severe pain and tenderness of the trunk rapidly develop in the most severe cases, probably as the result of intramuscular hæmorrhage Dyspnœa may be due to hæmorrhage into the respiratory muscles Restlessness, which is prominent may be the result of subarachnoid bleeding Hæmoptysis is common within an hour or so of the incident and tends to be repeated Dyspnœa becomes greatly accentuated in cases dying after 36–48 hours, and there is hæmoconcentration with rise in venous blood-pressure A large venesection may relieve these features In pulmonary concussion the hæmorrhages are progressive, and one of the main principles of treatment must be to immobilise the patient as soon as possible and to disturb him as little as possible for several days

LUNG IRRITANTS

Prof J SHAW DUNN stressed the importance of dosage of gas in the evolution of symptoms High concentrations of phosgene elicit violent respiratory disturbance with œdema and over-distension of the lungs ending fatally in a few hours, lower concentrations cause early dyspnœa and steadily progressive œdema which may be fatal but is susceptible to treatment by venesection and oxygen Bronchial spasm is an early feature and contributes to the sensation of tightness in the chest and difficulty of drawing breath Bronchopneumonia is a serious though later addition, and may occur more readily in man than in animals owing to auto-infection or droplet infection in wards It adds considerably to the risk of fatality and also where recovery takes place to the likelihood of permanent damage to the lungs Pulmonary œdema is the most fundamental problem in poisoning by lung irritants Capillaries in the juxta-bronchiolar alveoli show dilatation and engorgement with thrombosis in some and œdema fluid comes from those capillaries through which blood continues to flow The more severe the dosage of gas the greater the dilatation and engorgement of capillaries and cardio-respiratory embarrassment is more severe though œdema is less in bulk In discussing the part played by altered capillary into the plasma to be used again in the synthesis of fresh hæmoglobin , the bilirubin is partly excreted as urobilin and urobilinogen in the fæces and urine and partly reabsorbed, being presumably available again for resynthesis into protoporphyrin, though the intermediate stages are not clear All this is the background for Gruneberg's view that his siderocytes indicate some disturbance of hæmoglobin synthesis It is certainly possible that derangement of this iron cycle may occur in disease Clinical and cytological differentiation of anæmias takes us only part of the way , there is an important group in which the cytologist can only say that the bone-marrow shows red cells being formed normally but rather less or more actively than usual, as the case may be, without giving any indication of the cause of the anæmia Dreyfus[3] thinks with some reason that understanding and application of our increasing knowledge of the chemistry of hæmoglobin is one of the most promising means of learning more about this inadequately differentiated group

NON-SPECIFIC ULCERATION OF THE COLON

Barlow[4] has drawn attention to a little recognised form of acute abdomen, in which early operation is the only means of saving life, but which seems to baffle diagnosis It is caused by the acute perforation of a non malignant, non-specific ulcer of the colon In many cases the ulcer is in the cæcum, so that the clinical picture may suggest appendicitis in over a third of the reported cases in the cæcum and ascending colon this was the preoperative diagnosis Evidence may however be detected of free gas in the peritoneal cavity The pathological findings suggest that the condition is one of chronic ulceration with acute exacerbation leading to perforation, and it is possible for symptoms to be sufficient to call for laparotomy before actual perforation occurs The ulcer is funnel-shaped, thus differing from gastric and duodenal ulceration, which it otherwise resembles Barlow analyses 52 cases of simple ulcer of the cæcum and ascending colon, including 2 which he is personally reporting Although these are the common sites, the sigmoid colon and other parts may be affected, including the rectum Barlow suggests that the relative stasis determines the incidence in different sites in the colon The edge of the ulcer is hard, and the base at the end of the funnel shows active inflammation and is the position of perforation Pain in the chronic stage, before perforation, is far less severe than in gastric or duodenal ulceration , in fact, 66% of ulcers on the right side of the abdomen, and 81% of those on the left, were already perforated when first seen by a doctor Before perforation vague pains may suggest investigation of the intestinal tract, and a diagnosis such as carcinoma of the colon lead to laparotomy Once perforation has happened the urgency of operation seems as a rule to have been obvious That some cases died without operation Barlow attributes to the fact that the records go back more than thirty years The two facts that stand out most clearly from the records is that no case was correctly diagnosed prior to operation , and that no case not operated on survived Where the condition is suspected before the ulcer perforates the abdomen should be opened, because of the great risk of perforation Simple drainage has been uniformly unsuccessful Barlow advises resection and lateral anastomosis as the operation of choice in the absence of perforation After perforation one can choose between oversewing the ulcer and draining the pelvis, and exteriorising the bowel with or without a cæcostomy Barlow carried out resection, as for carcinoma of the cæcum—which indeed he suspected at operation—in his first case The second had several ulcers of the cæcum with acute inflammation of the cæcal wall Two of the ulcers had perforated He therefore closed the perforations and cæcum and ascending colon, suturing the bowel to Next day he opened the cæcum by diathermy Bo tions were successful He suggests that barium trast radiography might help in the preoperative di

POSTURAL DRAINAGE IN CHILDREN WITH BRONCHIECTASIS

In the conservative treatment of bro children postural drainage is often made difficult patient's lack of cooperation, or fails because remain undrained through the improper use of "Nelson bed" or similar tipping devices B Bonham-Carter[1] claim that more detailed anatomical diagnosis and the maintenance of the posture by a special device makes postural more worth while, whether used to effect a cure on own or as a preoperative procedure As regards nosis they set out the method used at the Hosp Sick Children, Great Ormond Street, for obt bronchograms, based on G S Erwin's work at Brompton Hospital[2] The patient is prepared for a by 18 hours' postural drainage daily to empty affected portion of lung General anæsthesia is emplo for children under ten years (ethyl chloride followed ether) and local anæsthesia to the larynx for o children After being tested for cocaine sensitivity child sucks a Decicain sweet Then, using a s with 1½ in of 1/10 in bore rubber tubing attached, p through the nose, 2–3 c cm of a 1% cocaine solution is in The oil used for the bronchogram is oleum iodis B P run in cold, one side only being done at one sit the volume required varying with the age of the ch If the tongue is pulled well forward by tongue forcep oil passes through the catheter and drops into the lary The position of the child depends on the part of the l which it is desired to fill, and Barsby and Bonham C set out some detailed anatomical considerations should be closely studied by anyone attempting method With carefully obtained taken as stereoscopic X-ray views, the physician a position to apply postural drainage intelligently affections of the upper lobes drainage is best effected allowing the children to run about For drainage of middle, ventral and anterior basic bronchi the should be on its back on a flat bed with the chest by a special wedge under the affected side The foot the bed should be raised eighteen inches to two feet the child's feet must be tied loosely to the foot of bed by straps attached to anklets of soft material draining the axillary basic, posterior basic and do bronchi the child should be placed on its face ove tipping device with the trunk at right angles to the l The special wedge is placed under the affected side the child is secured by attaching the feet to the foot of bed, with a strap like a martingale passing from the ce of the chest or back to the head of the bed Thi st can be conveniently attached to an ordinary strap jac commonly used for keeping children in bed In jacket two oblong pockets are made, front and back, into these a wedge made of firm sponge rubber is inse according to the position in which the child is to be l Eighteen hours a day in hospital or the entire night w at home are necessary to secure adequate drainage w is helped by the administration of a liquefying expec ant mixture

n pulmonary compression symptoms develop almost hately after the accident. Through it is difficult ess the importance of pulmonary fat-embolism, that the symptoms might closely resemble those osgene gassing, for they come on about the same and are characterised by severe pulmonary œdema, mia and right heart failure. The treatment, ver is similar for both. He advocated a critical of the pathogenesis of pulmonary œdema in abolism, since it might give some indication of the of phosgene œdema. In fat-embolism the fat is rritative and the changes are consequent on ilar occlusion and local anoxæmia, factors which ld be considered in phosgene poisoning. He had often ntered hæmoconcentration in the pulmonary lation in cases of pulmonary œdema, despite the nce of gross change in the peripheral circulation. uggested that hæmatocrit analysis of the blood in two circulations might be profitable. He, like Dr. orn had seen cases of so-called neurogenic pulmonary ma, and said the condition has been produced erimentally in America by Farber.

GENERAL DISCUSSION

urgeon Rear-Admiral C P. G **WAKELEY** said he l met with a rather different type of lung injury, in ich the damage was certainly inflicted from without ese men had been in the water near the place where pth charges were going off and said that when the arge went off they could feel the "kick" from it. me of them were brought in dead others died afterards They showed as a rule no extreme damage of e chest They often complained of abdominal pain, d often had hæmoptysis, hæmatemesis and diarrhœa t autopsy they showed the appearance of blast injuries f the lungs They also had other injuries, such as iptured liver and other abdominal traumata.

Surgeon Lieut-Commander G L. **FOSS** said he had rried out some experiments on the effect of adrenal rtical hormone in lewisite poisoning but he had not amined the medulla of the suprarenals.

Prof **SHAW DUNN** pointed out that the pressure in the od-vessels is not the only factor concerned in œdema, e rate of flow also plays an important part He was pressed with the importance of alternation in capillary atation. He understood that in the denervated lung alternation in capillaries can be observed This of urse might be explained by the total blood-supply to e lungs being much greater than in an intact lung suggested that if the alternation in bronchial activity s present in the human lung it should be observed by hiologists during screening, he had not heard of any ch alteration being observed in the human lung

Prof J H **GADDUM** said there is evidence that various ms of lung injury do liberate histamine and that it uld be interesting to know whether phosgene does s Laqueur and Magnus observed a primary fall of od pressure after phosgene, which may be due to eration of histamine

Dr **JOAN ROSS** dealt in detail with carbon-monoxide soning and the secondary pneumonia following blast jury of the lung In compression the hæmorrhages ay be bilateral and symmetrical, these are usually bpleural, and rib markings are usually seen, there is neral congestion of the lungs and often œdema, rdieu's spots are often seen, and there may be thrombsis of vessels In concussion, on the other hand, the morrhages are always bilateral and symmetrical and y subpleural hæmorrhage is present as an extension m deeper areas, there is general congestion of the ngs, but Tardieu's spots and thrombosis of vessels are t found Dr Ross had not seen the massive hilar morrhages described by Dr Osborn In the typical se of blast injury of the lung there are free red cells in e alveoli, but the alveolar walls are normal and there no œdema These are the changes found at the early ges In cases which survive longer the secondary anges which supervene are very like those seen in an dinary lobar pneumonia In the alveoli are red lls, fibrin and mononuclear cells It is difficult to say hat degree of fat-embolism will prove fatal Certainly t-embolism will not account for the hæmorrhages — lonel L E H **WHITBY** asked what she considered the urce c the fat was in the cases which showed fat in t capillaries.—Dr. Ross replied that in many such cases there were no fractures and the fat was only found in the pulmonary capillaries and not elsewhere in the body, its origin was unknown

Surgeon Lieutenant R. M. **CALDER** considered the mechanism for the absorption of fluid from the alveoli That such a mechanism exists in a normal lung is an old observation He had injected as much as 30 c cm of serum into a rabbit's trachea without killing it. After 3 hours about 30% of the injected fluid had disappeared, and 70% was away by 18 hours It was hoped to measure the absorption of fluid after phosgene in a similar way, but unfortunately most animals die after quite small injections when they have been previously exposed to phosgene. Another difficulty is that one does not know how much fluid is lost by evaporation Sir Joseph Barcroft calculated that on theoretical grounds a rabbit could evaporate as much as 25 c cm of water in a day. The main histological feature of such lungs is the intensity and speed of the phagocytic response Within 30 min the alveoli and septa contain large numbers of mononuclear cells where Trypan Blue has been added to the fluid these cells will nearly all contain granules of the dye. There is no dilatation of the lymphatics. This picture is in striking contrast to what is seen after phosgene where the alveoli are practically free of cells in the stage of œdema and the lymphatics are widely dilated The normal animal can remove from its lungs quantities of fluid larger than those found in animals dying from phosgene poisoning, this strongly suggests that after phosgene there must be some interference with the normal absorptive mechanism

A Note on Technique

In a short paper on technical methods in the study of the lung-irritant gases, Captain R H D **SHORT** said it may not be easy to distinguish between desquamation of the mucous membrane of bronchioles and spasm of bronchioles since both may exist at the same time The nuclei in desquamated epithelium will be pyknotic In the experimental animal which has received Trypan Blue intravenously the mucous membrane will show diffuse cytoplasmic staining In a series of rabbits exposed to 1 15,000 phosgene for 15 min and killed at varying times afterwards pulmonary collapse is a characteristic finding during the first 6 hours Its distribution is lobular The cavity of many alveoli is completely obliterated in others it is reduced by more than 50% It must therefore be decided whether this collapse is real or is due to faulty technique In rabbits in which the lungs have been removed without tying the trachea such a degree of collapse is not found and it is therefore probably not the result of faulty technique There are two possible causes for the collapse—spasm of the bronchioles and obstruction of the bronchiolar lumen by desquamated epithelium In rabbits and guineapigs which were given histamine intravenously, examination of the lungs showed a considerable degree of bronchiolar spasm There was practically no collapse It is probable that the alveolar collapse after exposure to phosgene is the result of a complete obstruction by desquamated epithelium of a bronchial lumen already reduced by spasm It has been found that alveolar exudate stains in a different manner according to the stage at which the animal has been killed after exposure Before 3–6 hours the exudate stains blue with Orange G and Aniline Blue, at about 6 hours it stains in alternating bands of yellow and blue, and when fully developed, from 12 hours onwards it stains yellow That this is not due to thickness of the section has been shown by staining sections 5 μ and 20 μ thick, which stain in the same way Protein films dried on slides and stained show that solutions containing under 0 5% protein will stain blue, those between 0 5% and 1% will show alternating bands of blue and yellow and those over 1% will stain yellow Solutions of the three plasma proteins show the same phenomenon, and films prepared from samples removed at intervals from plasma digested with a solution of trypsin behaved in the same way as a similar series where boiled trypsin solution was used The staining reaction is not due to breaking down of r [illegible] Though the basis of this staining reaction is appears to provide a semi quantitative method ing p [illegible] an exudates permeability in the production of pulmonary œdema Prof Shaw Dunn said that the amount of damage, though sufficient to determine abnormal escape of fluid for many hours, yet permits continued blood-flow There is no evidence that permanent structural change occurs in the alveolar walls The most prominent histological evidence of capillary damage is dilatation and congestion At any moment the total pulmonary blood-flow is being transmitted through only a proportion of the capillaries and not through the whole network Pulmonary capillaries in the gas lesion may thus be visualised as having

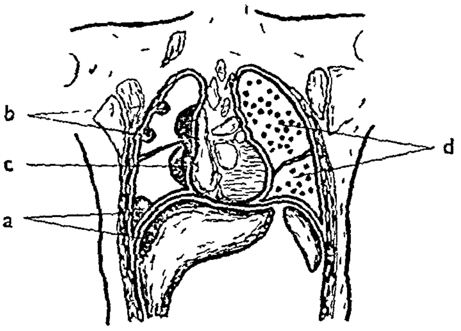
(1) a slower blood flow ,

(2) an increased blood content applied to a greatly increased filtering surface ,

(3) a higher lateral blood pressure, since capillary diameter is enlarged ,

(4) walls thinner than normally, due to the distension

These factors appear adequate to account for the leakage of fluid from the capillaries Escape of this plasma fluid into the air spaces is contributory to hæmoconcentration, and the increased viscosity of the blood which results doubtless accounts for embarrassment of the pulmonary circulation Another contributory factor is the greater pressure exerted on pulmonary capillaries by the fluid in the alveoli than by air Well-timed venesection, which is so valuable in the treatment of blue cyanosis in gassing, depends not only on alleviation of cardiac embarrassment by removal of blood from an overloaded venous system but also on the reduction of blood-volume which will favour return of fluid to the circulating blood, even from the lungs In the stage of grey cyanosis, however, peripheral circulatory collapse has set in and venesection is unlikely to be helpful Prof Shaw Dunn thought it unlikely that confusion might arise between the initial concussed state of blast patients and any stage of gas poisoning He agreed that the clinical conditions would become much more complex if the effects of poisonous gases were added to those of ordinary trauma, as might easily be the case in air attacks



Main Types of Hæmorrhagic Concussion of Lungs —The three primary lesions are shown on the right side (a) Phrenico costal sinus contusion with related liver damage (b) Two " rib markings " are shown in the upper lobe , these extend to a variable depth and tend to become confluent posteriorly where they may merge into (c) Massive hilar contusions The hilar lesion is most massive posteriorly The secondary lesion (d) is shown in the left lung, this is innumerable hæmorrhagic spots due to inhaled blood varying in size from about a pin's head to a silver threepence Their distribution is fairly uniform over one lobe, one lung or both lungs The variations evidently depend on the amount of blood entering the bronchi and the posture of the patient while the blood is in the bronchi

BLAST LESIONS OF THE LUNGS

Dr G R OSBORN outlined his experience of primary, secondary and reactionary lung lesions resulting from a bomb explosion (see figure) Primary features are (1) rib markings, best seen in infants, ill-defined in adults, single or multiple , with a location suggesting that they were inflicted with the lungs in the inspiratory position, (2) contusion of the phrenicocostal sinus , and (3) massive hilar contusion The last is of obscure origin and may possibly be explained by the penny experiment (if a penny is knocked against a row of pennies the end one only flies off , see Sutherland, G A *Lancet*, 1940, 2, 641) With a large compressing force, the alveoli with air locked in them behave like the pennies, and the force is transmitted to the deep parts of the lung in the region of the hilus In the larger primary lesions alveoli are packed with red corpuscles which without doubt have come from the alveolar capillaries, although the latter are so compressed that the holes through which they have escaped cannot be seen Inhalation of blood is a secondary lesion and results in scattering of blood throughout the lungs as small red spots R lesions are principally acute pulmonary œdema, ' pneumonia " and true pneumonia Œdema on and prove fatal within an hour, or it may not for several days Dr Osborn divided cases of pulmonary œdema into 3 groups (1) those to brain lesions, (2) those due to left ver and (3) those due to pulmonary causes Left failure is not a satisfactory explanation for all cases described lung œdema in a man of 29 with rupture aneurysm of the middle cerebral artery who organs were normal, and who had sustained no It is often possible to detect a nervous factor in which are apparently due to left ventricular pulmonary lesions Morphia is the only drug have an effect on the condition

PHOSGENE POISONING

Surgeon Commander ARCHIBALD FAIRLEY de an unusual case of human phosgene poisoning patient was an Oxford student, who was one of a pa round which a tube of phosgene was passed at a demo stration She was the first person to smell the pho A capillary tube of phosgene was simply cracked in glass bottle, and she then took a good sniff from t bottle and at once coughed She had no immedi symptoms, but later in the day began to cough and ha all the symptoms of acute asthma It is of course known what actual dose of phosgene she inhaled Sh then became acutely ill, breathing very rapidly, mak wheezing noises but showing no cyanosis She was ill that she had to be taken to a nursing home, where sh was given continuous oxygen for a week It is po that there was a neurotic element in her case Co mander Fairley carried out some experiments on goa to try to imitate the conditions under which the pati had inhaled phosgene The goats were fitted with rub respirators which were connected to bottles in wh similar capillary tubes of phosgene were brok Phosgene could be smelt in the air expired by the go Similar symptoms were produced to those found in th girl The goats began to breathe very quickly and we obviously ill and restless Blood-counts revealed n change The goats were killed later, and at autop showed no pulmonary œdema, except a very sli degree in one goat Then the experiment was repeat but the phosgene was first put in a Douglas bag, so th the dilution was much greater , this caused no symptom The capsules contained 30 mg of phosgene, which woul liberate 8 c cm of gas This is theoretically a fatal dos but of course we do not know whether the girl actual inhaled that amount The striking thing about th human case was the acute asthmatic attack, resemblin ordinary asthma

DIFFERENTIAL DIAGNOSIS

Prof J A RYLE said that those who had had clini experience of gas casualties should not find the differenti diagnosis of blast injuries and gas poisoning difficu The likelihood of meeting a combination of gas and bl effects was probably small The differential diagno would clearly be assisted by the history of the incide A case of blast is obviously ill from the start He w complain of pain and be breathless, and may ha hæmoptysis The symptoms of gas poisoning, on t other hand, are of later onset and will be unlikely include hæmoptysis or pain and in most cases of pho poisoning there will be a clear history of gas having be used As regards treatment, rest is the first esse for both types of case It is not known whether oxy is beneficial in blast injuries of the lung The clin appearance of cases suggests that they should be t with oxygen He had seen the B L B mask poo tolerated and wondered whether the old-fashioned n tube might be better in some cases He favoured S Dunn's view that the primary mechanism in pulmon œdema was capillary damage He did not think that œdema was due to heart failure The differen diagnosis of pulmonary concussion and phosgene poi ing should rest on (1) history, (2) the appearance of patient, and (3) symptoms and signs

Dr A H T ROBB SMITH agreed with Prof Hadfield about the findings in cases of blast injury o lungs He thought that, on the whole, sympt would not be confused with those of phosgene poiso

In England Now

nning Commentary by Peripatetic Correspondents

two outstanding memories of what the *Times* has to christen the Four Years War are my mother entiously following up the writing of a letter by ig the letter to which she had just replied into and going every Sunday morning to the post office id the war bulletin posted on the door Sunday papers were unheard of in our house though my r used to admit that there was much in his sister's ntion that it was a Monday morning paper which ight not to buy, because it had been printed on the ath All this seems absurdly remote from these , but it came back when I read Sir Kenneth Murchi i memoirs The generation which has grown up een the wars must sometimes wonder how that war arranged without the wireless The answer was—he public speech Murchison records how in 1918 sed to speak on behalf of the National War Savings mittee Among the points he was expected to ke were do not use tablecloths or buy new clothes id travel, *use less fuel, give up tobacco and use* ls instead of matches (sound familiar don't they?) describes how, in an interlude at a cinema, a pretty l performed tortuous dances and he gave a six-minute lress on the need for saving The B B C has abolished this and I can't see a modern cinema audience, lated with personal appeals from cabinet ministers, perial prime ministers and distinguished soldiers and ilors, welcoming another dose in the interval sandiched between two tunes on the organ

* * *

There are many pests about a hospital of all sorts, izes shapes and political creeds Even in the narrower ense of vermin there are several varieties to be encounered in and around the best of hospitals There are, course, the insect pests commonly associated with my life Their eradication is often difficult enough, it it is as nothing to the difficulties that meet our tempts to control the rabbits and rats Rabbits are erywhere and at this time of year particularly it is arcely possible to avoid tramping on them They ve voracious appetites, and the head gardener never ases to lament the damage they do to our crops ter the fashion of the times we have taken to growing tatoes, and even the shaws of these in their early days em to offer tempting bait to our bunny family Various perts have counselled different methods of approach me want to line our entire five-acre potato patch with shed wire, which would apparently make our already pensive crop wholly prohibitive in cost, apart altother from using wire that can probably be put to better rpose elsewhere Some think the rabbits should be ot, a time-consuming process not altogether free from nger in view of the uncertain marksmanship of our staff hers explain airily that the rabbits should be trapped This question of the trapping of vermin is one that we ve always approached with distrust Trapping, in y case, seems a puny weapon in a countryside so full of bbits as ours, though we have embarked on a course rabbit ensnarement that may ultimately save a few our potatoes and provide some protein to go with em Our rabbit traps have emanated from some ficial source and are presumably as effective as rabbit aps can be, but we encountered some weird and onderful traps in our earlier efforts to dispose of rats me of these are issued with codes of instructions that ould put to shame the prolix official pronouncements e receive from other sources There are instructions r unpacking the constituent parts of the traps, for ting the wire grids and the run-boards for the treatment the pivoted floor, which appears to be the crux of the echanism The floor is held firmly in the set position suction produced by boracic ointment applied to the ood strip on which the floor rests The success of the ap depends mainly on the delaying action of the ointent for without it the floor would begin to tilt slowly e a rat was fully over the pivot and the rat would cape It is naïvely explained that "Ointment of the lk of a large pea suffices to delay action of the floor til a full grown rat of about 18 ounces passes cometely over the pivot to the bait side in fact, half a inute may elapse ere the floor gives way suddenly and throws the rat into the tank in the interval of delay the rat will nibble at the bait and may be joined by another rat thus speeding the capture of both' On the subject of baiting the instructions are precise The trap may *be baited with a lump of brown bread or with oatmeal* for which a sprinkler container is provided Brown bread, it appears differs from the food usually accessible to rats in bulk form it cannot be carried away and this tends to the congregation of a number of rats at the bait until their combined weight causes the floor to give way When brown bread is not available, or fails to attract a red herring or kipper should be fixed on the spikes after rubbing it on the run-boards This all sounds straightforward and the story draws to a triumphal close To remove the rats the bottom of the tank should be raked slowly from side to side with a small planting fork or the like, all small rats being collected and the bodies disposed of in a furnace if possible"

Doubtless some elaborate mechanism for the mass execution of rats is necessary, since we are credibly informed that one good-going pair can be responsible for the production of something like 850 others in the course of a year The only trouble about our traps is that they do not work, possibly on account of some inherent defect in the trap or its setting, or from some superlative acumen or dexterity of our rodent population

* * *

Mrs Endhouse wife of a farm labourer lives about six miles from anywhere and is nearing the end of her third pregnancy Yesterday she wrote to say that her face was puffy and her legs swollen and could we do anything about it? Two of us answered the call prepared to give an anæsthetic and perform a surgical induction if necessary summoning the district nurse, who had to come six miles from another direction to help Mrs Endhouse proved hysterical and negative, she had albuminuria and a rising blood-pressure but she weren t goin' to 'ave nothin' done In that case we retorted she must go into hospital, but this also she flatly refused to do In vain we explained, entreated, implored and threatened Her husband and a neighbour had no better fortune and at the end of an hour and three-quarters of solid spadework she grudgingly conceded that she would have an enema if we liked We did not like but returned to the attack At the end of two hours we were exactly where we started and went home to think out the next move If we wash our hands of her, some other poor doctor will be obliged to take over and go through it all again If we leave her alone she may develop eclampsia and die quite unnecessarily What would you do chums?

* * *

As is perhaps natural my goats Sirene and All-Cleara are proving capricious They are tethered within comfortable reach of their sleeping quarters, an outsize dog-kennel formerly the abode of a quasi-mastiff now long since gathered Since we cannot offer them separate bedrooms both goats have to be tethered to one post by separate ropes so that either may turn in when she wants to without the other necessarily having to accompany her No fishing cast in the hands of the veriest *tyro could* rival the tangles my goats produce in their tethering ropes A fly on the end of a cast is a passive thing which permits itself to be slipped in and out of loops but not so a goat Just when you have reached a critical point in the process of disentanglement your goat gives an almighty heave, sits back on her haunches and pulls the whole thing tight again The only alternative is to detach the goat from the distal end and hold her between your knees while you get on with the rope, while you are doing this the other goat comes up and playfully butts you and/or her girl-friend to ensure that a difficult time is had by all As soon as you have got the lines clear both goats gallop joyfully to and fro repeatedly crossing in front of each other, and whenever possible incorporating any other obstacle within reach so that they are soon lying cheek by jowl in enforced intimacy and imminent danger of strangulation Another playful habit indulged in freely by both is to take flying leaps at and strive to obtain a foothold on top of the dog-kennel, knocking it over and inflicting further material damage on its already crazy roof Since this bulletin started the housemaid has reported that All-Cleara has broken loose I, for one, shall not care if she fails to return to her base

MAXILLO-FACIAL WOUNDS

WAR OFFICE MEMO

THE following memo on the preliminary treatment of maxillo-facial wounds has lately been circulated by the War Office

Only first-aid treatment is practicable until the patients arrive at the main dressing station, which may be some hours after the receipt of the wound Early treatment is directed to saving life, the two main aims being to prevent suffocation and control hæmorrhage General treatment to prevent shock is given by rest, warmth and sedatives

Respiratory obstruction—Loss of control of the tongue displacement of bony tissue or both may be sufficient to produce obstruction of the air-passages Attention should be paid to the possible presence of foreign bodies—e g , fragments of teeth or dentures—which should be carefully removed Posture is of vital importance and the patient should be placed on the stretcher in the prone or semi-prone position to prevent the tongue falling back If he is sitting up, or is able to walk the wounded man should do so with his head bent forward and downwards Stretcher bearers must be trained in the transportation of men in the prone or semi-prone position

Hæmorrhage—Correct posture will help to control hæmorrhage by keeping the tongue forward Ligature of visible bleeding vessels may be practicable at the advanced dressing station

Bandaging—The ordinary four-tailed bandage should never be used unless applied under the chin, as it is likely to increase the displacement of the fragments by backward pressure The "Barrel" and "Hamilton" types are very suitable and are easily and rapidly applied A useful external support is Elastoplast—a good grip can be obtained in the shaved temporal areas and the scalp left free In all cases the bandage should be applied under the chin in such a way as to give gentle upward support

Preliminary operative treatment—The main dressing station or the casualty clearing station is the first place where a dental officer will be available and his cooperation will be sought in every case After due attention has been given to shock, hæmorrhage and respiration, X-ray examination (both lateral and antero-posterior) should be made at the earliest opportunity

Preliminary operative treatment should be carried out as a rule under general anæsthesia, the surgeon and the dental surgeon working together The throat should be packed with one piece of 6 in roll gauze during intratracheal anæsthesia until the jaws are ready for intermaxillary wiring, when the packing should be removed A long stout stitch may usefully be passed through the dorsum of the tongue and the ends secured This stitch must not be removed until the reflexes have fully returned after the operation Owing to mobility of the fragments great care is necessary when manipulating any form of gag Debridement should be more conservative than in the limbs and trunk, and is seldom necessary

INJURIES TO HARD TISSUES

Without loss of tissue—As far as possible, accurate apposition of fragments should be carried out A tooth in the actual line of fracture should be extracted (except when there is only one tooth on the distal fragment and its retention might temporarily assist in control) Fragments carrying teeth should be immobilised by interdental wiring with malleable stainless steel wire When, in cases of fracture of the mandible, intermaxillary interdental wiring is impossible (e g , where the superior maxilla is edentulous) the principle of maxillary wiring may be adopted One or more thin stainless steel wires are passed through the alveolar process and looped to furnish fixed points to which the interdentally wired fragments of the mandible can be attached to reduce and immobilise the central fragment

When teeth in the mandible are absent or have been destroyed it may be possible to modify the patient's denture or to use impression composition or gutta percha moulded inside the mouth, or in a Kingsley splint, to control the fragments

With loss of tissue—Only the smallest bony fragments which are completely separated from periosteal attachments should be removed The main fragments be fixed in normal occlusion with the opposing jaw their ends are exposed they should be covered mucous membrane by the suturing of mucous to mucous membrane or skin If necessary, any ends of exposed bone may be removed to relieve Even if the whole mental region is lost the ments should be held in normal occlusion Never bone fragments (with intervening loss) to fall to or great deformity and loss of function will Surgical wiring of bone fragments is absolutely indicated in all compound fractures of the mandible

INJURIES TO SOFT TISSUES

When there is no loss of tissue make a careful prima suture with accurate apposition of skin edges, using stitches placed as close to the edge of the wound possible When there is loss of tissue only such prima suture of the wound as can be done without any or closure of the mouth should be undertaken, thu loss of a third of the upper or lower lip, without su jacent fracture, may safely be sutured without detrime to subsequent treatment Suture of a lip, when there a compound fracture of the mandible should not attempted until complete control and repositioning the fragments have been obtained As a result of t neglect of this rule many cases have been admitted special centres with an encroachment on the oral open rendering subsequent repositioning of the bony fragme extremely difficult It is far better in these cases to all attention to repositioning the bone fragments and leave suturing soft tissue and plastic treatment for lat Suture of skin to mucous membrane around the mar of the defect is a valuable procedure in prevent infection and contraction of the soft tissues, either which will vitiate both hard and soft tissue replaceme

There is a high incidence of abscess formation after inju of the lower jaw and the advisability of providing subma bular drainage at the outset by the insertion of one or m tubes at likely sites should be considered The drink cup with about 3 in of free rubber tubing is a suitable met of presenting fluid diet well back in the throat A solutio sodium bicarbonate is especially recommended as a mo wash or for purposes of irrigation in addition to the ordin antiseptics The mouth should be irrigated after feeds means of a Higginson syringe Owing to the con dribbling of saliva in maxillo facial wounds the dressings rapidly soaked and frequent changing is necessary A jaconet or other waterproof bib should be worn to pro the clothing

At the first opportunity the patient should be evacu to a special maxillo-facial hospital or other hos where the services of a maxillo-facial team are availa

TUBERCULOSIS IN WALES

AT its annual meeting on Aug 1 Lord Davies, the presid urged the Welsh National Memorial Association to try o system of mass radiography He suggested that at first should concentrate on young people in the vulnerable groups—such as children leaving secondary schools students—and on contacts To examine the whole of W simultaneously twenty five units would probably be ne and he thought they might start with one radiological which would examine 100,000 cases in a year Dr D Powell, principal medical officer, pointed out that at many new cases would be discovered and reminded meeting that there was already a deficiency of 400 beds in W But he agreed that the ultimate advantage of the experi would be the early control of infection The preparation plan for the scheme was referred to the committee

The meeting also decided to send a resolution to Minister of Pensions asking that when men are discharged the services immediate steps should be taken so that the given proper treatment and that everything should be to alleviate suffering of dependants The association attention to their difficulty in finding nursing and dom staff for their hospitals If something were not done work would come to a standstill

Sully hospital has now been made a thoracic centr South Wales and arrangements are being made for tuberc officers to be called by E M S officers as consultants in of non tuberculous diseases of the [illegible] be su for admission to the hospitals verbrook for the bombed out Colonel Walter T said the waiting-list was a humanitarian, social onomic scandal which was not present in anything he same intensity in England save in the North oought the figures given by Mr Johnston were of the strain and stress on the national health ngitis was due to overcrowding paratyphoid to sanitation and tuberculosis was the danger signal alnutrition The Minister of Labour had said he d sooner have 10 000 extra rations than 10,000 workers, yet there were only 2 canteens at Scottish But feeding on the spot is a sure method of giving lementary rations to those who really need them r K Lindsay asked if something like a welfare rtment could not be set up in the Scottish education rtment He would like to see the whole of proba- included under education Dr H B Morgan lored the organisation of fracture treatment in Scot- l which he said was far below the standard set up the Delevingne committee He had yet to hear of a abilitation centre in Scotland Mr G Buchanan ed the hurried debate with a protest that there had not n time to say a word on perhaps the gravest matter Scotland—juvenile crime

QUESTION TIME

Milk for Next Winter

Major G Lloyd George replying to a question said btantial quantities of condensed milk have been manu- tured in this country during the summer and large quantities e being supplied from overseas There is therefore no ason to expect that anyone will be short of milk during the ming winter, but individuals may have to consume rather ore condensed milk and rather less liquid milk than they ave been accustomed to do In view of the perishable ature of milk and the paramount importance of avoiding aste we are satisfied that a formal rationing scheme is ndesirable One pint of liquid milk per day will continue to available to all expectant mothers and infants up to five ars of age under the provisions of the present National ilk Scheme Supplies of half a pint per day will also be ailable for children and adolescents up to the end of their venteenth year on payment of the full current prices To able liquid milk to be provided for those priority classes id to assist in the distribution of liquid milk to the remainder the population, all members of the public will be required register for milk. The cheese ration will be increased to 3 oz. r head for the ordinary consumer as from Aug 25 The t on of 8 oz. for the priority classes will remain unchanged

National Wheatmeal Loaf

Miss E. Rathbone asked whether Major Lloyd George s aware that a large proportion of the bread shops in ondon were refusing to stock the national wheatmeal loaf, d in view of the large public expenditure in advertisements ging the public to buy this loaf, will he consider making its pply compulsory —Major Lloyd George replied The wer to the first and last part of the question is no More an 3000 bakers and bread shops as well as the majority of wholesalers and coöperative societies are already coöperat- g with my department in popularising the sale of national eatmeal bread in London.

Pharmacy and Medicines Bill

Sir E. Graham-Little asked the Minister of Health if he ould now name the bodies who were parties to the agreement rived at, after long consultation, before the Pharmacy and edicines Bill reached the House, and if he was aware that e agreement was accepted by all the parties concerned only h regard to the original clause 7, and that the other clauses re negotiated separately by different interests —Mr E own replied According to my information the following ties signified their agreement with the proposals which m the basis of clause 9 of the bill (clause 7 in the bill as troduced) Proprietary Association of Great Britain, harmaceutical Society, National Pharmaceutical Union, ottish Pharmaceutical Federation, Company Chemists sociation, Wholesale Drug Trade Association, National ederation of Grocers and Provision Dealers Associations, arliamentary Committee of the Coöperative Congress, and e Association of Wholesale Druggists and Manufacturers of edicinal Preparations The remaining clauses of the bill were ot the subject of a general agreement of this kind but in ertain instances the parties most closely concerned have been onsulted

Cost of National Health Insurance

During the year ended Dec 31 1940, £17,948,000 was expended in Great Britain on sickness and disablement benefits under the National Health Insurance Acts

There are in England and Wales 17 290 doctors under contract with insurance committees In 1940 they were paid £7,674 127 for treatment, £251,938 for drugs, and £256 767 for mileage, making a total of £8,182,832 (Mr Brown replying to Mr W Thorne)

Medical Examination of Recruits

Mr Rhys Davies asked the Minister of Labour whether, in order to assist medical boards in testing men for service in the Army, he would request approved societies to supply the boards with the medical history of each case so as to avoid as far as possible passing those whose medical history made it obvious that they were physically incapable of making efficient soldiers —Mr Bevin replied The investigation of previous medical history forms an important part of the medical examination, which includes careful questioning on this matter by the examining doctors In addition, every man is informed, when called for medical examination, that the medical board will be prepared to give careful consideration to medical evidence regarding any serious illnesses or disabilities from which he has suffered, and he is also asked to complete a questionnaire designed to elicit information as to certain aspects of his previous medical history I have given careful consideration to the suggestion but I am advised that it would not supplement the information already obtained to an extent sufficient to counterbalance the administrative difficulties in the way of its adoption.

Mr James Griffiths asked the Minister what steps were taken by the medical boards, Armed Forces Act, to prevent men with tendencies to tuberculosis being recruited into the forces, and if it was proposed to improve the system of examination in view of the number of men discharged from the forces on account of tuberculosis —Mr Bevin replied Arrangements have been made for notification to the medical boards of particulars of every man of military age whose name appears on the tuberculosis register kept under the Public Health (Tuberculosis) Regulations, 1930 In addition, every man examined is asked to state if he has ever suffered from tuberculosis or received treatment for tuberculosis or suspected tuberculosis, and careful attention is given to any medical certificates which may be produced. It is generally recognised that incipient or latent pulmonary tuberculosis cannot usually be diagnosed by ordinary clinical examination, but wherever there is reason to suspect tuberculosis the board refers the man for radiological or other special examination by the tuberculosis officer of the local authority of the area in which he lives A suggestion that the chest of every recruit should be radiologically examined was fully considered last year by the medical advisory committee under the chairmanship of Lord Horder, and the committee decided that its adoption was impracticable

Tuberculous Ex-Service Men in Wales

Mr Griffiths asked the Minister of Pensions if his attention had been called to the resolution passed by the Welsh National Memorial Association, urging him to make provision for men discharged from the forces suffering from tuberculosis[1], what provisions existed to provide such treatment, and what further steps he was taking in the matter —Sir W Womersley replied I have not received a copy of the resolution Residential treatment for tuberculosis in ex-Service men falls to be provided by the local health authorities under their general tuberculosis scheme, and where such treatment is provided for a man whose need for treatment is due to war service the local authority is entitled to submit to the ministry a claim for reimbursement of the cost of the treatment These arrangements have worked and are working satisfactorily In Wales the arrangements for residential treatment of ex Service men are made through the Welsh National Memorial Association and so far as I am aware there has been no difficulty in arranging any residential treatment required by our pensioners

Mr Griffiths asked the Minister of Health if his attention had been called to the report of the Welsh National Memorial Association, indicating a deficiency of 400 beds for waiting tuberculosis cases, and what steps were being taken to provide additional accommodation.—Mr Brown replied I have seen a press report that a statement was made at a recent meeting of the association to the effect indicated. The question of

Parliament

The New Pharmacy Act

SINCE the second reading of the Pharmacy and Medicines Bill in the Lords a conference has taken place between the Government and Viscount PLUMER and those for whom he was acting, and most of their difficulties have been removed On Aug 5 Viscount SIMON intimated that the amendments which he would move on behalf of the Government fell into two classes Some technical amendments relating to clause 1 of the bill were the result of careful revision by the Home Office Amendments had also been devised to meet difficulties in the minds of those interested in herbal remedies Clause 8, as the bill was originally drafted provided that the medicine must have a label affixed which must show "the appropriate designation of the substance so recommended or of each of the active constituents thereof" It had been feared that this might be understood to mean that it was necessary to state what were the chemical constituents, notwithstanding that there might be chemical changes after the contents had been put together It was proposed to amend the clause so that it would be enough to say that the contents, for example, had been made of dandelion root Viscount PLUMER pointed out that the "drying, crushing or comminuting" named in subsection 4 of the clause were all dry processes The herbalists therefore desired an amendment inserting the words "macerating, infusing, boiling, decocting, distilling, pressing and expressing" and a further amendment inserting the words "with or without the addition as preservatives of glycerin, alcohol, esters of parahydroxy-benzoic acid, or such other preservative as the Minister of Health may sanction" Lord SIMON resisted the first amendment, and Lord HORDER said he must also strongly contest it He was sympathetic to those who wished to take their medicines from a complicated mixture of ingredients prepared in a complicated fashion The herbalists had been given a certain amount of what they asked for by the insertion of the phrase "or of each of the ingredients of which it is compounded" But now they were asking that processes should be permissible in preparing those ingredients which were calculated to so change and confuse the ingredients as to make it impossible to state what they finally were The action of these preservatives on the questionable derivatives remaining after macerating, infusing, boiling and so on would render the principle of the bill which called for disclosure of no effect The first amendment was withdrawn and the second was negatived

The bill received the Royal Assent on Aug 7

Need for Organised Fracture Service

In the House of Commons on Aug 7, Dr H B Morgan amplified the plea he had made in the debate on the Scottish estimate for a bigger and better fracture service A B M A committee in 1935 had stated that there was inadequate organisation of fracture treatment, imperfect surgical treatment even in the best hospitals, and failure in giving proper functional activity to prevent the injured parts from becoming stiff This chaos was not due to lack of surgical technique or prowess, but to lack of organisation The committee recommended segregation of fracture cases in one department, aftercare, the keeping of perfect records, and the establishment of rehabilitation centres As a result of this report the Delevingne committee was appointed by the Government and after a thorough inquiry they confirmed the B M A committee's recommendations The Delevingne committee classified hospitals in six grades, and only in grade-1 hospitals were the principles of treatment recommended by the committee followed There were then only three hospitals in Wales where adequate treatment could be obtained and in Scotland there was only one grade-1 hospital Recently the Secretary of State for Scotland stated that there were six new orthopædic hospitals in Scotland, but he did not say whether they were up to grade-1 standard In England only 74 hospitals were in grade 1 out of a total of 1100 Dr Morgan thought the present Minister of Health and the Parliamentary Secretary had tried hard to improve things, but they had been hampered by the conditions in the voluntary hospitals and by lack of
Even the Voluntary Hospitals Association were satisfied with the position, but they had not the
for the necessary extensions The rapid recovery
injured workers was vital and Dr Morgan urged
Government to show what progress had been made
regard to grade-1 hospitals Other grades were
portant The supplementation of orthopædic
was not enough, more organisation was needed
the Minister of Health and his advisers accept
reserve the recommendations of the B M A
committee, and was it the policy of the
implement those recommendations as soon as possible
especially those of the Delevingne committee with regard to hospital grading? Dr Morgan finished his speech with a volley of questions as to the working of what he called this Peter Pan service

Miss F HORSBRUGH wished Dr Morgan would put some of these anxieties out of his mind and tell the ministry which were the hospitals where he alleged the treatment was not what it ought to be She thought the Emergency Hospital Service had been one of the marvels of our war organisation Orthopædic centres had not been graded according to the report of the Delevingne committee because they were now working under war-time conditions and the ministry did not want to rely on hospitals in vulnerable areas for long term work The work had been divided up into orthopædic centres and into A and B fracture departments The B centres were short-term ones because they were generally in vulnerable areas Apart from the ministry's consultant advisers they had regional consultants to see that this type of treatment should be organised and the patients properly segregated In the orthopædic centres there were about 5000 beds and in the fracture A departments 5000 beds, which would give many thousands of people a chance to get this up-to-date and carefully arranged treatment Miss Horsbrugh expressed her pride in the 10,000 new beds though Dr Morgan still thought it was a tortoise pace

Scottish Health

Scots M P s regarded the meagre ration of six hours allotted on July 30 to the debates on the health, education and agriculture of their native land as an example of Sassenach parsimony In the absence of reports for 1940 and 1941 they were resentful that Mr T JOHNSTON should have to introduce the estimates with a survey lasting only fifteen minutes But in a year full of the restrictions and disabilities of war he was satisfied that an efficient public-health service had saved the country a major epidemic Tuberculosis figures were increasing diphtheria figures were higher than before, and paratyphoid, cerebrospinal fever and influenza were slightly up, but scarlet fever, measles and whooping-cough were decreasing During the year 500,000 children, about half of the total, had already been immunised for diphtheria, and local authorities during the school holidays were concentrating on the pre-school children Under the E M S, beds had been reserved for possible and unknown war casualties but Mr Johnston agreed that a much larger proportion of these beds ought to be made available for the civilian patients who were on the waiting-lists of other hospitals Scotland now had seven new first-class hospitals and twenty new annexes to existing hospitals Many thousands of beds were available and doctors and hospital authorities in Scotland had been notified that these beds were open to the patients on their waiting-lists He hoped these new hospitals would be the nucleus of a great organisation for a united attack upon physical suffering

Turning to housing he said that in the Clyde four hostel camps are being provided, each accommodating 480 people and capable of being converted into 2-3 roomed houses after the war There were a hundred hostels for children in use and another fifty ready During the year 14,206 new houses had been completed Evacuees included 40,000 pre-school and 80,000 school children Out of the total school population of 743,80 only 3600 were receiving no education, but there were 160,200 half-timers

Mr H MCNEILL in an eloquent maiden speech said that our treatment of the homeless might mean the difference between defeat and victory, and appealed fo

ORBID RED-CELL DEVELOPMENT AND THE TREATMENT OF ANÆMIA

M C G ISRAËLS, M.D M SC MANC, M.R.C P
ASSISTANT DIRECTOR OF THE DEPARTMENT OF CLINICAL
INVESTIGATION AND RESEARCH, UNIVERSITY AND
ROYAL INFIRMARY, MANCHESTER

> 'The scientific journey has no end It has only halting ices—points at which the traveller can look round and vey"—SHERRINGTON

IN the last ten years there has been much progress in ematology and much re-appraisal of former ideas so at a survey now seems timely. A useful sample of the ews of a decade ago is provided by Witts's Goulstonian ctures to the Royal College of Physicians in 1932 [30] Witts represented red blood-cell development as a series f successive stages represented by the scheme

$$\text{Reticulo-endothelial cell} \xrightarrow{1} \text{megaloblast} \xrightarrow{2} \text{normoblast} \xrightarrow{3} \text{erythrocyte}$$

An important group of anæmias was shown to be due to defective development of erythrocytes, and the pathology of this group was simply conceived of as a failure of maturation at the various stages failure of stage 1 caused aplastic anæmia, failure of stage 2 produced pernicious anæmia, when stage 3 failed anæmia typified by the microcytic iron-deficiency anæmias occurred Anæmia of increasing severity might start with stage 3 defective and later involve stage 2 or even 1—a species of "shift to the left" Therapy was equally simply indicated so it is not surprising that this pathological scheme was widely utilised and is, in fact, still reproduced in most English textbooks

A considerable volume of clinical and pathological work, especially that correlated with studies of bone-marrow obtained by sternal biopsy, has now shown that this simple scheme is inadequate and it is interesting that this further work had tended to confirm the observations of earlier workers on the development of the erythrocyte, observations that were passed over by Doan and co-workers,[7] on whose results Witts based his ideas The more complex developmental schemes now put forward [2 12 23] are a return towards those of hæmatological pioneers like Naegeli and Ferrata This return has brought with it a recrudescence of the confusion in cell nomenclature which was the bane of the days of the "peripheral hæmatologists," and this in itself has tended to obscure the value of these advances and prevent their adequate application by clinical workers In spite of differences in nomenclature, a scheme of red blood-cell development similar in outline to that given below is at present accepted by a majority of hæmatologists

Technical methods are important in hæmatology since different methods produce different microscopical appearances There are two groups of methods—the normal histological technique of wet fixation and preparation of smears or sections, and the dry-smear method exemplified by the usual way of preparing blood films The pros and cons of the methods were thoroughly discussed by Downey,[5] and briefly it may be said that sections are necessary for comparing changes in the arrangement of the marrow cells whereas dry smears are best for showing cellular detail and differentiating between the various cell types The cell types mentioned here in the description of blood cell development have been defined by the study of dry-smear preparations of blood or bone marrow obtained by sternal puncture (see Israëls) [12]

NORMAL AND ABNORMAL RED-CELL DEVELOPMENT

In the adult, red blood-cells are formed only in the bone-marrow The most primitive cell formed there that concerns us now is the *hæmocytoblast*, so-called because it is found in hyperplasia of all blood-cell types [12 27] It is a large cell with a rim of deeply basophilic cytoplasm and a large purple-staining nucleus of rather indefinite pattern and containing nucleoli Its subsequent development is shown in the figure, maturation involves changes in the nuclear pattern leading eventually to shrinkage and fragmentation and in the cytoplasm where the development of hæmoglobin causes a change in the staining reaction from basophilic to eosinophilic Normally these changes in nucleus and cytoplasm progress in a parallel manner, but in pathological states the correlation is disturbed

From the hæmocytoblast a *pro-erythroblast* develops, differing in being somewhat smaller and having a well-defined network nuclear pattern—nucleoli are present Ordinarily the pro-erythroblast gives rise to a series of *normoblasts* In the early normoblasts the nuclear pattern is coarser from coalescence of the network pattern, and nucleoli have disappeared, the cytoplasm is still deeply basophilic The intermediate normoblasts show progressive shrinkage of the nucleus to a cart-wheel pattern and the cytoplasm varies from moderate basophilia to purplish polychromatic staining The late normoblast has a featureless nucleus and the cytoplasm becomes completely eosinophilic Finally the nucleus is lost and the erythrocyte appears When prolonged normal hyperplasia of the hæmopoietic marrow has occurred hæmoglobin may appear in the cytoplasm at an earlier stage and normoblasts with well-patterned nuclei are found with polychromatic or even eosinophilic cytoplasm [13], the late normoblasts and the erythrocytes developing from these prematurely hæmoglobinised cells tend to be somewhat larger than usual

In pernicious and allied anæmias an entirely different set of cells appears in the marrow—the *megaloblasts* The early megaloblasts resemble the pro-erythroblasts in size and staining properties, but the nucleus shows a more open network pattern and there is no coalescence of the chromatin as seen in the early normoblasts; nucleoli are absent As maturation proceeds the chromatin strands become finer and more separate so that the intermediate megaloblast has a highly characteristic open network nucleus; hæmoglobin appears early and these cells are usually polychromatic and may be fully eosinophilic; the cells are large compared with the corresponding normoblasts In the late stage the nucleus collapses and is commonly eccentrically placed in a large eosinophilic cell, some traces of nuclear pattern may remain, finally the developed erythrocyte is a relatively large cell There is much more variation in cell-size and in correlation of nuclear pattern and hæmoglobinisation of the cytoplasm among megaloblasts than among normoblasts Mitotic figures are found in both series up to and including the intermediate stage

The descriptions given here apply to typical cells, but since continuous change occurs along the lines of development indicated by arrows in the diagram, cells intermediate between the typical stages are always to be found

The theory that the appearance of the megaloblasts represents a return to embryonic blood-formation was advanced by Ferrata [7] and Naegeli [19] In the early embryo hæmocytoblasts are present in the walls of the blood islands of the yolk-sac and from them the first erythroblasts are formed—they are often called "primitive megaloblasts" At about the sixth week of development, hæmocytoblasts appear in the liver and give rise to a second generation of erythroblasts different from the megaloblasts—these are the permanent or "definitive" generation and are called normoblasts so long as they have nuclei (Downey) [6] Later normoblast formation begins in the bone-marrow and after the 23rd week liver hæmopoiesis gradually fades out [8] It is suggested that the megaloblasts of pernicious anæmia are identical with the primitive megaloblasts of the embryo,[6 7 17 19 27] and it is certainly a striking coincidence that when the hæmopoietic liver factor fails, blood-cells should appear that resemble those which serve the organism in its pre hepatic stage of development This idea, though attractive, is not yet firmly established and some workers, notably Maximow,[15] regard the megaloblasts of pernicious anæmia as purely pathological cells.

This description of the scheme of normal and pathological red blood-cell development has been given first since it defines the names used for the various cells (the term *erythroblast* is used generically for all the nucleated red-cell precursors) The evidence on which the scheme is based may now be considered

FOUR TYPES OF PATHOLOGICAL ERYTHROPOIESIS

In untreated pernicious anæmia the marrow shows megaloblastic hyperplasia—that is to say, all types of

Obituary

VINCENT JOSEPH REDMAN SHERIDAN

D S C , M B EDIN , SURGEON LIEUTENANT, R N

Surgeon Lieutenant V J R Sheridan, who was lost when H M S *Kelly* sank off Crete, was the second son of Dr John Sheridan of Barnsley Born in 1914 he was educated at Stonyhurst and graduated at Edinburgh in 1936 He joined the medical service of the Royal Navy a year later and after a course at Chatham was posted to the China Station In October, 1938, when H M S *Sandpiper* was bombed by Japanese aircraft he was commended for his cool and excellent conduct In January, 1940, he won his D S C for further services in connexion with the Sino-Japanese conflict Sheridan returned to England in March of last year and was appointed to H M S *Kelly* When the ship was torpedoed on May 9 the sick bay was wrecked and Sheridan had to look after the wounded by the light of a torch, but the captain of the flotilla later wrote that he was untiring in his efforts to ease their pain

Captain **Frank Robert Oliver Hayward**, whose death is announced, was in practice before the war at Chelmsford, where he was anæsthetist to the Chelmsford Hospital He volunteered for service the day war was declared and was posted as medical officer to a yeomanry regiment He qualified M R C S from Guy's Hospital in 1932 He was 33 and leaves his widow with a young son

Captain **Robert Thomson Easton**, who died of wounds in the Middle East in May, was born in 1903 He graduated M B at the University of Aberdeen in 1927 and held house-appointments at the Royal Infirmary, Oldham, later becoming an assistant resident medical officer at St Mary's Hospital, Plaistow He joined the R A M C T A shortly before the outbreak of war and last year was promoted captain

Lieutenant **Thomas William Greatorex**, who is reported to have died of wounds, was the son of Dr R W Greatorex of Halifax He was born in 1914 and obtained his conjoint qualification last year He was gazetted lieutenant in the R A M C last December

Infectious Disease in England and Wales

WEEK ENDED AUGUST 2

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 863 , whooping-cough, 3731 , diphtheria, 727 , paratyphoid, 194 , typhoid, 34 , measles (excluding rubella), 3084 , pneumonia (primary or influenzal), 424 , puerperal pyrexia, 136 , cerebrospinal fever, 166 , poliomyelitis, 28 , polio-encephalitis, 5 , encephalitis lethargica, 5 , dysentery, 122 , ophthalmia neonatorum, 86 No case of cholera, plague or typhus fever was notified during the week

Notifications of paratyphoid for the second time showed a decrease Of the 194 cases, 25 were reported from the County of Chester (Birkenhead 7, Bebington 6) and 96 from Lancaster (Liverpool 70)

Deaths —In 126 great towns there were no deaths from enteric fever, 1 (0) from scarlet fever, 22 (2) from whooping-cough, 4 (0) from measles, 26 (2) from diphtheria, 31 (4) from diarrhœa and enteritis under 2 years, and 4 (0) from influenza The figures in parentheses are those for London itself

Tottenham reported 4 deaths from whooping cough, Sheffield 3 There were 3 fatal cases of diphtheria at Liverpool

The number of stillbirths notified during the week was 191 (corresponding to a rate of 41 per thousand total births), including 24 in London

The Index and title-page to Vol I, 1941, which was completed with the issue of June 28, will be ready shortly A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now

Births, Marriages and Deaths

BIRTHS

Black —On Aug 9, at Alresford, Hants, the wife of Temp Lt-Colonel J Gordon Black, R A M C —a daughter

Creighton —On June 7, at Nairobi, Kenya, the wife of Capt J O Creighton, E A A M C —a son

Crimmin —On Aug 8, at Woking, the wife of Major G W Crimmin, R A M C —a daughter

Morris —On Aug 3, the wife of Dr Lawrence Morris, of Bickenhall Mansions, W 1—a son

Pritchard —On Aug 5, at Hemel Hempstead, the wife of Dr J J Pritchard—a son

Rudd —On Aug 4, at Aberdeen, the wife of Major T N Rudd, R A M C —a daughter

Simmonds —On Aug 5, the wife of Dr F A H Simmons—a son

MARRIAGES

Golden—Waterson —On Aug 7, in London, Michael Golden, M R C S , to Diana Waterson

Mills—Davies —On July 26, in London, Reginald Peter Mills, M R C S , to Margaret Frances Steuart Davies

Whiteside—Spencer —On Aug 8, at Bradford on Avon, Wilts, Cecil Hamilton Whiteside, M R C S , captain R A M C , to Charlotte Spencer

DEATHS

Fulton —On Aug 5, Thomas Ronald Fulton, M B Glasg , of Sutton on Sea

Melville —On Aug 11, in Edinburgh, Kenmure Duncan Melville, M D Edin

O'Meara —On Aug 10, at Luton, John Morgan O'Meara, M D Lond

Rice Oxley —On Aug 10, at Chalfont St Peter Alfred James Rice Oxley, Kt , C B E , M A Oxfd, M D Dubl , M R C P , of Kensington, aged 85

Ridout —On Aug 9, Charles Archibald Scott Ridout, M S Lond , F R C S , of Southsea

Shires —On Aug 8, in London, Bertram Shires, M B Edin , D M R E

Verdon Roe —On Aug 7, Spencer Vernon Roe, M B Camb , of Sinnington, Yorks (formerly of Putney)

Waring —On Aug 9, at Maresfield, Anthony Henry Waring, D S O , M R C S , colonel, late R A M C , aged 69

Appointments

Brockington, C Fraser, M D Camb , *D P H* M O H for Warwickshire

Brown, K Carnarvon, M B Lond , *D A* R M O at Royal Northern Hospital, London

Ellis, G E D , M R C S , surgeon captain, R N retd asst M O (civil defence) for Brighton

Flecker, Margaret, M B , Adelaide R M O at the Emergency Maternity Hospital Gilsland

Gillespie J E O'N , M D Dubl , D P M medical registrar at the National Temperance Hospital, London

Herapath, J C , B M Oxfd, M B Wales junior assistant in the medical unit, Welsh National School of Medicine, Cardiff

Jenkins, Ritchie, M B Wales R M O at Cardiff Royal Infirmary

Lindsay, James, M D Glasg examining factory surgeon for Royton, Lancashire

Scott, Edith, M B Aberd R M O at Leicester General Hospital

Shooter, R A , M B Camb R M O at the Royal West Sussex Hospital, Chichester

Smith, J B Gurney, L M S S A asst R M O at Norwich Infirmary

Todd, R M , M B Camb R M O at Leicester General Hospital

Royal Sussex County Hospital, Brighton —As an extension of the Latilla department of physical medicine, its founder, Mrs Herbert Latilla, and her two daughters have presented to the hospital a motor van equipped with apparatus for electrical treatment, which daily visits centres in country districts, avoiding towns where treatment is already available All new patients must first attend at the hospital and pass through the almoner's department Overlapping and abuse of the service are thus avoided Masseuses are selected from the staff of the department and the van is driven by members of the W V S

The **Fellowship of Medicine and Post Graduate Medical Association** has arranged the following M R C P courses neurology at the West End Hospital for Nervous Diseases (Aug 26–Sept 19, Tuesdays and Fridays at 3 30 P M), heart diseases at the Royal Chest Hospital (Aug 27–Sept 17, Wednesdays at 3 30 P M), chest and heart diseases at the London Chest Hospital (Sept 2–25, Tuesdays and Thursdays at 2 P M) They will also hold the following final F R C S courses clinical course at St Mary Islington Hospital (Sept 3–24, Wednesdays at 2 P M), orthopædics at Royal National Orthopædic Hospital, Stanmore (Sept 6–27, Saturdays at 2 15 P M), and a comprehensive course at the Royal Cancer Hospital (Sept 29–Oct 17, every morning) Further information may be had from the secretary of the fellowship, 1, Wimpole Street, London, W 1

MORBID ERYTHROPOIESIS

BONE-MARROW TYPE	CLINICAL TYPES
Failure of normal maturation of pro-erythroblasts · suppression of normoblasts, deflection of maturation to megaloblasts	(a) Pernicious anæmia due to deficiency of liver-principle (b) Achrestic anæmia refractory to treatment due to non-utilisation of liver-principle (c) Anæmia due to dietary deficiency or failure of absorption of liver-principle
Failure of maturation of normoblasts: hyperplastic but deformed normoblasts and inadequately hæmoglobinated microcytes	Iron-deficiency anæmias
Hyperplastic normal maturation: increased normoblasts and pro-erythroblasts, often unusually early hæmoglobin formation in normoblasts	(a) Anæmias due to prolonged peripheral blood loss by chronic hæmorrhage intravascular lysis (hæmolytic anæmia) purpura, malignancy, cirrhosis of liver, leukæmia, &c (b) Anæmias of unknown ætiology refractory to treatment, pseudo aplastic
4 *General failure of erythropoiesis*: diminished or completely absent erythroblasts when present all normoblasts	Aplastic anæmias of primary type and those secondary to action of drugs or toxins secondary hypoplasia in leukæmia or splenic anæmia

Blood-picture Group 1 always megalocytic with colour-index over 1 Group 2 always microcytic with colour index under 1 Groups 3 and 4 usually normocytic colour index about 1 but may be over 1 and there may be megalocytosis in some cases especially in group 3

Treatment Liver, or desiccated stomach treatment is only appropriate in group 1 iron therapy is specific in group 2 in groups 3 and 4 treatment of the anæmia takes second place to action against the cause of the anæmia if known, blood-transfusions and iron treatment are indicated.

blasts with suppression of normoblast development and hyperplasia of megaloblasts,

2 Failure of maturation of normoblasts with hyperplastic but distorted development of normoblasts leading to the formation of inadequately hæmoglobinised microcytes,

3 Hyperplastic normal maturation, which if sufficiently severe and prolonged leads to the appearance of many early erythroblasts and unusually early hæmoglobin formation in the normoblasts,

4 General failure or erythropoiesis, of varying degree

Clinical conditions corresponding to these groups are given. Group 1 comprises pernicious and allied anæmias due to deficiency or disturbed action of the hæmopoietic liver-principle, group 2 corresponds to the iron-deficiency anæmias, group 3 changes are found in a variety of anæmias characterised by vigorous erythropoietic response to loss of red blood-cells—liver-deficiency plays no part here, group 4 comprises the idiopathic and secondary aplastic anæmias Attention is drawn to the refractory cases occurring in groups 1 and 3

Treatment of an anæmia varies according to the pathological group into which it falls Specific liver or desiccated stomach treatment is only appropriate in group 1

I am indebted to Dr John F Wilkinson and other members of the honorary staff of the Manchester Royal Infirmary for allowing me access to their patients Part of this work was carried out while holding a Foulerton research fellowship of the Royal Society

MOTOR NEURONE DEGENERATION TREATED WITH VITAMIN E

C Worster-Drought.
M D CAMB, F.R C.P
PHYSICIAN TO THE WEST END HOSPITAL FOR NERVOUS DISEASES

M.D GLASG, M.R.C P, D.P H.
MEDICAL REGISTRAR TO THE HOSPITAL

This clinical investigation was undertaken to ascertain the possible value of vitamin E in the treatment of motor neurone degeneration (progressive muscular atrophy, amyotrophic lateral sclerosis and progressive bulbar paralysis) A series of 25 cases of different forms of the disease have been treated for periods ranging from 5 to 10 months with vitamin E (α-tocopherol acetate) in doses of either 18 mg or 30 mg daily, and the results have been assessed

The assumption that vitamin E is of therapeutic value in motor neurone degeneration rests on the following experimental and clinical evidence

EXPERIMENTAL EVIDENCE

Evans and Burr (1928) first noted the occurrence of a *nutritional muscular dystrophy in young rats* deprived of vitamin E in their diet, and whose mother had been given only just enough of the vitamin to produce a litter The onset of the muscular paresis was sudden on or about the twentieth day of life, if the animal survived the paralysis appeared to be self-limiting Pathological examinations showed severe degeneration of the skeletal muscles but the central nervous system was unaffected the terminal portions of the peripheral nerves and the end-plates were found to be intact in the midst of necrotic muscle cells The muscular dystrophy could be prevented if wheat-germ oil or vitamin-E concentrates were administered to either mother or young during the period of lactation. Similar muscular lesions have been produced in ducklings guineapigs and rabbits reared under comparable conditions

Older rats observed by Einarson and Ringsted (1938) showed changes in the central nervous system in addition to those in the skeletal muscles In the earliest phase of the disorder they describe characteristic lesions in the *posterior spinal nerve-roots and posterior columns of the spinal cord* These are later succeeded by degeneration of the anterior horn cells and anterior spinal nerve-roots The third phase which is inconstant is distinguished by involvement of the pyramidal tracts Einarson and Ringsted consider the pathological findings as representing a process resembling a combination of tabes dorsalis and amyotrophic lateral sclerosis The muscular changes, they state although ultimately resembling those of a muscular atrophy of spinal origin, in the earlier stages approximate more closely to a muscular dystrophy. They suggest the possibility of a true mixed phenomenon —a combination of muscular dystrophy and amyotrophic lateral sclerosis

While vitamin E is capable of preventing the disease if given sufficiently early and in some animals is of curative value in others the prolonged and concentrated administration of the vitamin has failed to influence the established condition. This does not necessarily disprove that the essential ætiological factor is a vitamin-E deficiency Goettsch and Pappenheimer (1931) and Morgulis and Spencer (1936), however, claim that the nutritional muscular dystrophy cannot be considered

megaloblasts are present together with the more primitive pro-erythroblasts and some hæmocytoblasts, normoblasts are few and only of intermediate or late types, every stage of transition from hæmocytoblast to late megaloblast can often be seen, and the megaloblasts show characteristically variable hæmoglobinisation When the specific liver factor is given in proper doses a remarkable change comes over the marrow, sometimes within 24 hours [25] Early normoblasts appear in increasing numbers and then intermediate normoblasts, many showing early hæmoglobinisation, the megaloblasts decrease in number About the time of the reticulocyte peak in the blood, the marrow picture shows a complete reversal There is now a normoblastic marrow with only a few intermediate and late megaloblasts remaining, pro-erythroblasts and some hæmocytoblasts are still present and show mitosis As recovery proceeds this normoblastic hyperplasia dies away in its turn and the marrow returns towards a normal picture [2,12,20,25,26] These findings suggest that the liver-principle is necessary for the maturation of normoblasts from the pro-erythroblast When the liver-principle is deficient megaloblasts appear in an attempt to make up for the lost normoblasts

Megaloblastic hyperplasia of the marrow may also occur when, because of dietary deficiency, liver-principle cannot be produced [3,28], or when proper absorption from the alimentary tract is interfered with, as in sprue [21,29] or after gastro-intestinal operations [1] Normoblastic marrow can be restored with liver treatment

Hence megaloblastic marrow is an indication—the only certain indication—for liver treatment But the expected result does not always emerge, for there is a group of cases which are refractory to treatment, sometimes temporarily, sometimes permanently This group has been named achrestic anæmia by Israels and Wilkinson [14,16] who suggested that these patients were unable to utilise the liver-principle known to be present in adequate amounts Megaloblasts have not been certainly identified in any other types of anæmia (except the very rare acute erythræmia) [9,11] The erythroblasts appearing in all other primary and secondary anæmias are always normoblasts and pro-erythroblasts

Iron-deficiency anæmia is an example of failure of maturation of the normoblasts Bodley Scott [24] recently pointed out that though the marrow is hyperplastic the intermediate normoblasts are small, distorted and poorly hæmoglobinated, and give rise to the characteristic microcytes Sufficiently energetic iron therapy restores normal erythropoiesis When peripheral loss of erythrocytes is prolonged and severe, as in hæmolytic anæmias, there is again an intense normoblastic hyperplasia in the marrow, but this time they are larger than usual, their nuclei are well-patterned and there is often sufficient hæmoglobin in their cytoplasm to cause advanced polychromatic or even eosinophilic staining, pro-erythroblasts and even hæmocytoblasts are usually present [12,13] There is no evidence of liver-principle deficiency in this group The treatment is that of the primary condition causing the loss of blood-cells plus administration of iron to provide for the exceptionally active erythropoiesis Here again there occurs a group of refractory patients with normoblastic marrow, in whom no evidence of undue peripheral blood loss can be found, who do not respond to treatment, and who, if supported by blood may eventually recover, such cases have been called "pseudo-aplastic" [15,22]

Thus hyperplasia of the erythropoietic tissue may megaloblastic or normoblastic, the primitive erythroblasts being present in both The former occurs only when the hæmopoietic liver-principle is absent action is disturbed, all others fall into the latter "Shift to the left," caused for instance by prolonged blood loss, leads to the appearance of increased numbers of primitive normoblasts and pro erythroblasts never leads to the appearance of megaloblasts, and there is no convincing evidence that megaloblasts and normoblasts are interchangeable

Finally there are the conditions in which the erythropoietic marrow is hypoplastic or completely aplastic Such red blood-cell development as remains proceeds along the normoblastic line, and there are all grades of hypoplasia shading down to complete aplasia There may be patches of hyperplasia which will be misleading if punctured at sternal biopsy, but in progressing cases diminution of erythropoieses is always seen after an interval This group includes primary aplastic anæmia and secondary anæmias caused by the depressing action of drugs or toxins on erythropoiesis The primary aplasias can only be treated by blood transfusion, the secondary group are treated according to the cause, and transfusions to tide over difficult periods together with iron when erythropoiesis recovers is a rational plan of treatment

Experience has shown that there are four main types of pathological erythropoiesis (1) hyperplastic *but with failure of normal maturation of pro erythroblasts*, (2) hyperplastic with failure of maturation of normoblasts, (3) hyperplastic erythropoiesis with normal maturation, and (4) general failure of erythropoiesis The clinical syndromes corresponding to these pathological types are given in the Table on the opposite page

Into a scheme such as this the majority of cases of anæmia will be found to fit Some diseases provoke erythropoietic changes in more than one category Thus the anæmia accompanying splenic anæmia cirrhosis of the liver or leukæmia may in one patient be of group 3, in another group 4, the anæmia following gastric resection may be group 1 or 2 Sometimes more than one pathological group is involved, as in some patients with anæmia of nutritional origin But on the whole the pathological type corresponds to one or other of these groups and when the group is decided the appropriate line of treatment is clearly indicated, a more certain indication being thus obtained than from the blood-picture alone, especially when there is any doubt or obscurity in diagnosis

SUMMARY

A scheme of normal and pathological erythropoiesis is proposed, which shows that disease may cause changes in the development of the normoblastic group of cells, or maturation may be deflected to a megaloblastic group—regarded by some as a return to the first type of embryonic blood-cell development

Four main groups of pathological erythropoiesis are distinguished —

1 Failure of maturation of pro-erythro

6–9 months Evidence of an advance in the disease s seen in 5 cases examined after this period of treat- nt, and 1 case showed no change in symptoms or ysical signs In 2 cases there appeared to be some provement in gait with a raised level of general health, d 1 patient remained more or less stationary but with more cheerful outlook Details of the last 3 cases are follows —

CASE 1 —A woman, aged 42, presented the extraordinary mbination of Cushing's syndrome (pituitary basophil lenoma), and motor neurone degeneration, which had made its ppearance at the remarkably early age of 11 Examination April, 1940, showed weakness and atrophy of the small uscles of the hands and a spastic paresis of the lower limbs ith bilateral extensor plantar reflexes Wheat germ oil apsules, 1 t d s, were prescribed (equivalent to 18 mg ocopherol daily), after 2 months, tocopherol acetate, 0 mg daily, was given instead While in hospital the patient was depressed and irritable, and indeed, before her admission he had been under observation for her mental condition After 4 months' vitamin E therapy no change in the physical indings was noted, although her gait had slightly improved Her mental state had responded very satisfactorily, she was now much happier and her periodic emotional outbursts were ess frequent and less violent

CASE 2 —A man, aged 59, seen in May, 1940, when the condition had been present for 8 months He had gross wasting of the small muscles of the hands and of the forearms, both pectoralis major muscles and less severe wasting of the leg muscles He was given α tocopherol acetate, 30 mg daily, until December, 1940 At the end of this period there had been no advance in the loss of muscle substance but possibly some increase in the weakness The patient said he had greatly improved in spirits and general health In March, 1941, he wrote from Dorset to say that he continued in good health and seemed to be walking better

CASE 3 —A man, aged 69 In July, 1940, 8 months after the onset of illness, clinical examination showed weakness and wasting of the muscles of the shoulder girdle and the hypothenar eminences, and loss of power in the legs with fibrillation but no muscular atrophy Administration of α-tocopherol acetate, 30 mg daily, was begun in July and continued until the middle of December, 1940 There was no change in the disease, but a great improvement in his general health and he was now more cheerful

AMYOTROPHIC LATERAL SCLEROSIS

Paraplegia of upper neurone type was the predominant clinical manifestation in 7 of the cases treated, 6 were men and 1 a woman, aged from 45 to 52 After 6–9 months' treatment, 5 cases showed evidence that the disease was steadily advancing, 1, in spite of some advance in muscular atrophy, showed a striking amelioration in general health and mental outlook In the remaining 2, details of which are given below, the clinical condition had definitely improved

CASE 4 —A man, aged 45, in whom the disease began in April, 1940 In May, 1940, he had slight wasting and weakness of the interossei and lumbrical muscles, with spastic paraplegia, both plantar reflexes were extensor and the abdominal reflexes were absent Treatment with α tocopherol acetate, 30 mg daily, was continued until December, 1940, when there was some improvement in power of the lower limbs and in walking, while the early wasting of the hand muscles was less evident His general health had also improved and he was more cheerful

CASE 5 —A man, aged 50, who first experienced weakness of the lower limbs 18 months before beginning vitamin-E therapy in June, 1940 Examination showed a spastic paraplegia but no muscular wasting in any part of the body He could walk only with assistance After 6 months' treatment with α tocopherol acetate, 30 mg daily, he could walk the length of the ward several times by himself with a stick but there was no change in the physical signs of a bilateral pyramidal lesion At first sight this patient's neurological condition seems to have been benefited by vitamin-E therapy, but such a conclusion cannot be accepted unreservedly For the 18 months before his admission he had been confined to bed and had become depressed and despondent The interest and encouragement shown him in hospital stimulated his desire and his efforts to improve, and the undoubted improvement in his mental outlook had a similar effect

DISCUSSION

Vitamin E was administered to the patients in two forms—as wheat-germ oil and α-tocopherol acetate In 1936, Evans, Emerson and Emerson succeeded in isolating from wheat-germ oil two alcohols both of which possessed the biological properties of vitamin E and to which they gave the names of α- and β-tocopherol respectively, α-tocopherol has since been synthesised and has been proved to be as active (by the fertility test in animals) as the vitamin obtained from natural sources The acetate of α-tocopherol is a very stable form Each capsule of the wheat-germ oil we used is stated to have a standardised tocopherol content of 6 mg In addition to vitamin E, wheat-germ oil contains other active factors, such as vitamin B_6 Antopol and Schotland (1940) report beneficial effects from the use of vitamin B_6 in cases of muscular dystrophy In consequence, reports of the value of wheat germ oil in neuromuscular disorders must be accepted with reserve as evidence of the efficacy of vitamin E, since other principles may participate or even be entirely responsible for the alleged improvement

The cause of motor neurone degeneration still remains obscure Various hypotheses have been presented but none is wholly acceptable No definite evidence exists in support of an infective agent or toxin The view has been advanced that the disease is of the nature of an abiotrophy, but Wilson (1940) considered such a theory untenable in view of the distribution of the lesions He pointed out that the degenerative changes are not confined to the motor system nor are they clearly systematised, the process being diffuse in many zones On the results of the experimental work on animals, some grounds exist for the postulation of vitamin-E deficiency as part of the underlying ætiology Vitamin E is very stable to heat, light and desiccation, but—as Bicknell argues—it is readily decomposed in the presence of salts and fats, especially when the fats become rancid It has never been conclusively demonstrated, however, what minimum quantities of this vitamin are essential in the human body, nor that a deficiency produces untoward effects The difficulties in estimating the content of vitamin E in the blood, and the scanty investigations in normal subjects, account for the lack of detailed evidence Vitamins may possibly act as therapeutic agents, irrespective of whether or not there is a deficiency in the body, so that our inability to prove a vitamin-E deficiency in motor neurone degeneration does not rule out the possible value of the vitamin in treatment

The prognosis of motor neurone degeneration is always grave, although the rate of progress varies Death may occur in a few months, or only after many years Periods during which no advance of the disease takes place are by no means uncommon, so that in those of our cases in which the condition has become stationary it cannot be claimed that vitamin E necessarily produced this effect Clinical methods were relied on in the observations of the course of the malady An attempt was made to aid assessment of progress by estimating the urinary creatine and creatinine but this proved unsuccessful, partly because we were unable to control the patients' diets and partly on account of the difficulty in estimating urinary outputs

The general result of vitamin-E treatment has been disappointing, only 3 of the 25 cases showing some improvement In one of these (case 5) psychologic factors influencing the result have already been discussed, and it is doubtful whether the response could be attributed entirely to the vitamin E Case 4 improved both as regards spastic paraplegia and muscular atrophy, and it seems reasonable to assume that the favourable response in this case was dependent on the vitamin-E therapy In case 2 we had to rely on the patient's report of his improvement since distance from London precluded clinical examination All 3 of these cases had been treated with 30 mg of α-tocopherol acetate daily for 6–9 months · 2 other cases in the series remained more or less stationary over periods of 5 and 6 months respectively, and another (case 1) showed slight improvement in gait but no change in physical signs after 5 months' treatment It is noteworthy that all 9 cases of bulbar paralysis became definitely worse as solely dependent on the absence of vitamin E, they think the disorder should be regarded rather as a multiple deficiency disease This view has been challenged by Mackenzie, Levine and McCollum (1940), who state that they have been able to cure the muscular dystrophy of rabbits raised on identical vitamin-deficient diets by the administration of vitamin E (α-tocopherol) alone

It is well known that in the absence of vitamins other than vitamin E in a diet, paralytic syndromes are liable to arise, but these syndromes can be distinguished from the form of vitamin-E deficiency under discussion Thus while the animals deprived of vitamin E were normal in every respect apart from the muscular and nervous lesions, the paralysis consequent on the absence of vitamin B or C from the diet is only part of a profound constitutional change with emaciation, invariably ending fatally

The spontaneous arrest of the muscular dystrophy in young rats deprived of vitamin E has been mentioned, Abeile (1934) found that rats reared on a diet deficient in vitamin A showed—in addition to a disabling paralysis—profound loss of weight and xerophthalmia Finally Evans and Burr were unable to influence the incidence of the muscular dystrophy in young rats by the administration of vitamins A, B, C and D, but vitamin E was found to be effective

The neuromuscular disorder resulting from vitamin-E deficiency in animals seems to vary according to the particular class of animal and to some extent with the period of life at which the deprivation occurs Pappenheimer (1940) has recently reviewed the various forms of disorder hitherto described For instance, while the adult hen manifests no abnormality when deprived of vitamin E newborn chicks develop an encephalomalacia, the essential pathological lesion being an ischæmic necrosis An entirely different response is observed in the turkey, in which the central nervous system and skeletal muscles escape but the smooth muscle of the gizzard undergoes a patchy hyaline necrosis

Experimental evidence thus indicates that animals, as a result of vitamin-E deficiency, may develop a muscular dystrophy and degenerative changes in the central nervous system Further, that the nature and extent of the degenerative lesions vary with the class and age of the animal

CLINICAL EVIDENCE

Bicknell (1940) treated several cases of muscular dystrophy with fresh dried whole wheat-germ oil, ½ oz twice daily In addition, he placed 4 cases of amyotrophic lateral sclerosis on similar treatment, 2 of these patients died, but some clinical improvement was noted in the 2 remaining He suggests that a large supply of vitamin E may be of value in all degenerative conditions of the muscular or nervous systems Demole (1940) supports Bicknell's assertion Wechsler (1940) records 2 cases of amyotrophic lateral sclerosis which were seen to improve when given synthetic α-tocopherol 3 mg thrice daily. In a subsequent communication (1940) he claims improvement of varying degrees in 11 of 20 cases of amyotrophic lateral sclerosis The treatment consisted in a daily dose of 30 mg α-tocopherol acetate (later increased to 50 mg), a diet rich in vitamin E, bile-salts to increase the absorption of the fat-soluble vitamin, and the whole vitamin-B complex In addition, every patient received 2 teaspoonfuls of whole wheat-germ oil daily, and in about half the cases 50 mg of tocopherol in oil was injected intramuscularly each day

Shelden (1940) obtained negative results in 18 patients, 10 of whom were suffering from amyotrophic lateral sclerosis and 8 from muscular dystrophy, but hopes that future research may reveal some combination of this vitamin with other essential nutrient materials which may prove more efficacious A family is reported by Donovan (1940) in which the father and daughter had lordosis and the son muscular dystrophy Whole wheat-germ oil was prescribed, and all 3 cases showed improvement in their general health and felt more energetic Stone (1940) noted improvement in muscular strength and texture in 7 patients—5 with muscular dystrophy, 1 with muscular wasting as a sequel of multiple neuritis and 1 with muscular atrophy following poliomyelitis—as the result of treatment with wheat-germ oil, 1 capsule thrice daily Spies and Vilter (1940)

aged from 42 to 59, and 1 woman who show
muscular atrophy, especially of the intrin
both hands, and a mild upper neurone pa
unusually early age of 25 In all cases
described below, treatment with tocopherol

r 6–9 months Evidence of an advance in the disease as seen in 5 cases examined after this period of treat-ent, and 1 case showed no change in symptoms or ysical signs In 2 cases there appeared to be some nprovement in gait with a raised level of general health, nd 1 patient remained more or less stationary but with more cheerful outlook Details of the last 3 cases are s follows —

Case 1 —A woman, aged 42, presented the extraordinary ombination of Cushing's syndrome (pituitary basophil denoma), and motor neurone degeneration, which had made its ppearance at the remarkably early age of 11 Examination April, 1940, showed weakness and atrophy of the small uscles of the hands and a spastic paresis of the lower limbs ith bilateral extensor plantar reflexes Wheat germ oil apsules, 1 t d s, were prescribed (equivalent to 18 mg ocopherol daily), after 2 months, tocopherol acetate, 0 mg daily, was given instead. While in hospital the patient as depressed and irritable, and indeed, before her admission he had been under observation for her mental condition fter 4 months' vitamin E therapy no change in the physical indings was noted, although her gait had slightly improved Her mental state had responded very satisfactorily, she was ow much happier and her periodic emotional outbursts were ess frequent and less violent

Case 2 —A man, aged 59, seen in May, 1940, when the ondition had been present for 8 months He had gross vasting of the small muscles of the hands and of the forearms, oth pectoralis major muscles and less severe wasting of the eg muscles He was given α tocopherol acetate, 30 mg laily, until December, 1940 At the end of this period there ad been no advance in the loss of muscle substance but ossibly some increase in the weakness The patient said he ad greatly improved in spirits and general health In March, 1941, he wrote from Dorset to say that he continued n good health and seemed to be walking better

Case 3 —A man, aged 69 In July, 1940, 8 months after the onset of illness, clinical examination showed weakness and wasting of the muscles of the shoulder girdle and the hypothenar eminences, and loss of power in the legs with fibrillation but no muscular atrophy Administration of α tocopherol acetate, 30 mg daily, was begun in July and continued until the middle of December, 1940 There was no change in the disease, but a great improvement in his general health and he was now more cheerful

AMYOTROPHIC LATERAL SCLEROSIS

Paraplegia of upper neurone type was the predominant clinical manifestation in 7 of the cases treated, 6 were men and 1 a woman, aged from 45 to 52 After 6–9 months' treatment 5 cases showed evidence that the disease was steadily advancing, 1, in spite of some advance in muscular atrophy, showed a striking amelioration in general health and mental outlook In the remaining 2, details of which are given below, the clinical condition had definitely improved

Case 4 —A man, aged 45, in whom the disease began in April, 1940 In May, 1940, he had slight wasting and weakness of the interossei and lumbrical muscles, with spastic paraplegia, both plantar reflexes were extensor and the abdominal reflexes were absent Treatment with α tocopherol acetate, 30 mg daily, was continued until December, 1940, when there was some improvement in power of the lower limbs and in walking, while the early wasting of the hand muscles was less evident His general health had also improved and he was more cheerful

Case 5 —A man, aged 50, who first experienced weakness of the lower limbs 18 months before beginning vitamin-E therapy in June, 1940 Examination showed a spastic paraplegia but no muscular wasting in any part of the body He could walk only with assistance After 6 months' treatment with α tocopherol acetate, 30 mg daily, he could walk the length of the ward several times by himself with a stick, but there was no change in the physical signs of a bilateral pyramidal lesion At first sight this patient's neurological condition seems to have been benefited by vitamin-E therapy, but such a conclusion cannot be accepted unreservedly For the 18 months before his admission he had been confined to bed and had become depressed and despondent The interest and encouragement shown him in hospital stimulated his desire and his efforts to improve, and the undoubted improvement in his mental outlook had a similar effect

DISCUSSION

Vitamin E was administered to the patients in two forms—as wheat-germ oil and α-tocopherol acetate In 1936, Evans, Emerson and Emerson succeeded in isolating from wheat-germ oil two alcohols both of which possessed the biological properties of vitamin E and to which they gave the names of α- and β-tocopherol respectively; α-tocopherol has since been synthesised and has been proved to be as active (by the fertility test in animals) as the vitamin obtained from natural sources The acetate of α-tocopherol is a very stable form Each capsule of the wheat-germ oil we used is stated to have a standardised tocopherol content of 6 mg In addition to vitamin E, wheat-germ oil contains other active factors, such as vitamin B_6 Antopol and Schotland (1940) report beneficial effects from the use of vitamin B_6 in cases of muscular dystrophy In consequence, reports of the value of wheat germ oil in neuromuscular disorders must be accepted with reserve as evidence of the efficacy of vitamin E, since other principles may participate or even be entirely responsible for the alleged improvement

The cause of motor neurone degeneration still remains obscure Various hypotheses have been presented but none is wholly acceptable No definite evidence exists in support of an infective agent or toxin The view has been advanced that the disease is of the nature of an abiotrophy, but Wilson (1940) considered such a theory untenable in view of the distribution of the lesions He pointed out that the degenerative changes are not confined to the motor system nor are they clearly systematised, the process being diffuse in many zones On the results of the experimental work on animals, some grounds exist for the postulation of vitamin-E deficiency as part of the underlying ætiology Vitamin E is very stable to heat, light and desiccation, but—as Bicknell argues—it is readily decomposed in the presence of salts and fats, especially when the fats become rancid It has never been conclusively demonstrated, however, what minimum quantities of this vitamin are essential in the human body, nor that a deficiency produces untoward effects The difficulties in estimating the content of vitamin E in the blood, and the scanty investigations in normal subjects, account for the lack of detailed evidence Vitamins may possibly act as therapeutic agents, irrespective of whether or not there is a deficiency in the body, so that our inability to prove a vitamin-E deficiency in motor neurone degeneration does not rule out the possible value of the vitamin in treatment

The prognosis of motor neurone degeneration is always grave although the rate of progress varies Death may occur in a few months, or only after many years Periods during which no advance of the disease takes place are by no means uncommon, so that in those of our cases in which the condition has become stationary it cannot be claimed that vitamin E necessarily produced this effect Clinical methods were relied on in the observations of the course of the malady An attempt was made to aid assessment of progress by estimating the urinary creatine and creatinine but this proved unsuccessful, partly because we were unable to control the patients' diets and partly on account of the difficulty in estimating urinary outputs

The general result of vitamin-E treatment has been disappointing, only 3 of the 25 cases showing some improvement In one of these (case 5) psychologic factors influencing the result have already been discussed, and it is doubtful whether the response could be attributed entirely to the vitamin E Case 4 improved both as regards spastic paraplegia and muscular atrophy, and it seems reasonable to assume that the favourable response in this case was dependent on the vitamin-E therapy In case 2 we had to rely on the patient's report of his improvement since distance from London precluded clinical examination All 3 of these cases had been treated with 30 mg of α-tocopherol acetate daily for 6–9 months, 2 other cases in the series remained more or less stationary over periods of 5 and 6 months respectively and another (case 1) showed slight improvement in gait but no change in physical signs after 5 months' treatment It is noteworthy that all 9 cases of bulbar paralysis became definitely worse as solely dependent on the absence of vitamin E , they think the disorder should be regarded rather as a multiple deficiency disease This view has been challenged by Mackenzie, Levine and McCollum (1940), who state that they have been able to cure the muscular dystrophy of rabbits raised on identical vitamin-deficient diets by the administration of vitamin E (α-tocopherol) alone

It is well known that in the absence of vitamins other than vitamin E in a diet, paralytic syndromes are liable to arise, but these syndromes can be distinguished from the form of vitamin-E deficiency under discussion Thus while the animals deprived of vitamin E were normal in every respect apart from the muscular and nervous lesions, the paralysis consequent on the absence of vitamin B or C from the diet is only part of a profound constitutional change with emaciation, invariably ending fatally

The spontaneous arrest of the muscular dystrophy in young rats deprived of vitamin E has been mentioned , Aberle (1934) found that rats reared on a diet deficient in vitamin A showed—in addition to a disabling paralysis—profound loss of weight and xerophthalmia Finally, Evans and Burr were unable to influence the incidence of the muscular dystrophy in young rats by the administration of vitamins A, B, C and D , but vitamin E was found to be effective

The neuromuscular disorder resulting from vitamin-E deficiency in animals seems to vary according to the particular class of animal and to some extent with the period of life at which the deprivation occurs Pappenheimer (1940) has recently reviewed the various forms of disorder hitherto described For instance, while the adult hen manifests no abnormality when deprived of vitamin E newborn chicks develop an encephalomalacia, the essential pathological lesion being an ischæmic necrosis An entirely different response is observed in the turkey, in which the central nervous system and skeletal muscles escape but the smooth muscle of the gizzard undergoes a patchy hyaline necrosis

Experimental evidence thus indicates that animals, as a result of vitamin-E deficiency, may develop a muscular dystrophy and degenerative changes in the central nervous system Further, that the nature and extent of the degenerative lesions vary with the class and age of the animal

CLINICAL EVIDENCE

Bicknell (1940) treated several cases of muscular dystrophy with fresh dried whole wheat-germ oil, ½ oz twice daily In addition, he placed 4 cases of amyotrophic lateral sclerosis on similar treatment , 2 of these patients died, but some clinical improvement was noted in the 2 remaining He suggests that a large supply of vitamin E may be of value in all degenerative conditions of the muscular or nervous systems Demole (1940) supports Bicknell's assertion Wechsler (1940) records 2 cases of amyotrophic lateral sclerosis which were seen to improve when given synthetic α-tocopherol 3 mg thrice daily In a subsequent communication (1940) he claims improvement of varying degrees in 11 of 20 cases of amyotrophic lateral sclerosis The treatment consisted in a daily dose of 30 mg α-tocopherol acetate (later increased to 50 mg), a diet rich in vitamin E, bile-salts to increase the absorption of the fat-soluble vitamin, and the whole vitamin-B complex In addition, every patient received 2 teaspoonfuls of whole wheat-germ oil daily, and in about half the cases 50 mg of tocopherol in oil was injected intramuscularly each day

Shelden (1940) obtained negative results in 18 patients, 10 of whom were suffering from amyotrophic lateral sclerosis and 8 from muscular dystrophy, but hopes that future research may reveal some combination of this vitamin with other essential nutrient materials which may prove more efficacious A family is reported by Donovan (1940) in which the father and daughter had lordosis and the son muscular dystrophy Whole wheat-germ oil was prescribed, and all 3 cases showed improvement in their general health and felt more energetic Stone (1940) noted improvement in muscular strength and texture in 7 patients—5 with muscular dystrophy, 1 with muscular wasting as a sequel of multiple neuritis and 1 with muscular atrophy following poliomyelitis—as the result of treatment with wheat-germ oil, 1 capsule thrice daily Spies and Vilter (1940) were impressed by the striking general improvement in chronically ill-nourished people treated with α-tocopherol Taylor (1940) points out that in Lahore the incidence of muscular dystrophies, tabes dorsalis and amyotrophic lateral sclerosis is about the same as that in any London general hospital He found the diets of such cases to contain adequate amounts of vitamin E, and he therefore doubts the validity of the theory that vitamin E deficiency is the cause of certain neuromuscular disorders

Denker and Scheinman (1941) treated 11 cases of amyotrophic lateral sclerosis with α-tocopherol, administered orally, parenterally or by both routes Each patient received a total dosage of 100 mg each day, but no therapeutic results of any value were noted From their observations on 6 cases treated for periods varying from 6 to 12 months, Ferrabie, Klingman and Frantz (1941) concluded that vitamin E and vitamin B_6 preparations, even when given in large amounts, failed to influence the course of either amyotrophic lateral sclerosis or muscular dystrophy

PRESENT INVESTIGATION

The 25 cases in this series' are grouped under three headings according to the part of the neuromuscular system most affected by the degeneration, as bulbar paralysis, progressive muscular atrophy and amyotrophic lateral sclerosis The last term is sometimes used to include all manifestations of motor neurone degeneration, but it will be restricted here to cases in which a lesion of the pyramidal tracts is the predominant clinical feature Occasionally it is difficult to distinguish between the pure spastic paraplegia of amyotrophic lateral sclerosis, with no definite muscular wasting, and certain cases of disseminated sclerosis, especially those in which paraplegia is not associated with signs of incoordination, bladder disturbances or remission The diagnosis in some such cases must remain a matter of personal opinion In this study, a diagnosis of motor neurone degeneration has been accepted in cases of upper neurone paraplegia in which the onset has been after middle age , the deterioration has been steady and relentless, and there have been no symptoms, signs or history to suggest disseminated sclerosis

Owing to restriction in space, it has not been possible to include details of all cases , only 5 special examples have been selected All systems other than the neuromuscular system showed no abnormalities , the cerebrospinal fluid was examined in every case and was normal , the blood Wassermann reaction was negative in all cases Muscular fibrillation was noted in every case where evidence of involvement of the anterior horn cells existed, and will therefore be referred to only in the exceptional cases

BULBAR PARALYSIS

The 9 cases of bulbar paralysis treated included 6 me and 3 women, their ages ranging from 50 to 64 A showed the usual symptoms of dysarthria and dysphag with glossolabial paresis, and most of them had differe degrees of spinal motor neurone degeneration show itself by atrophy of the intrinsic muscles of the han fibrillation in some muscle groups or an early parapleg with extensor plantar reflexes In 8 cases 30 mg α-tocopherol acetate was given daily for 6–9 month the ninth case received wheat-germ oil equivalent 18 mg of tocopherol daily for 10 months While s under treatment 3 of the patients died, but each had tak vitamin E for more than 8 months The remaining patients showed a steady increase in the degree of bul paralysis even during treatment , only 1 case show some improvement in his sense of well-being, in spite retrogression in the neurological condition

PROGRESSIVE MUSCULAR ATROPHY

In 9 cases the predominant clinical features w muscular weakness and atrophy with fibrillation , had evidence of additional upper motor neurone chan in the lateral columns There were 6 men and 2 wom aged from 42 to 59, and 1 woman who showed pronoun muscular atrophy, especially of the intrinsic muscles both hands, and a mild upper neurone paraplegia at unusually early age of 25 In all cases except the described below, treatment with tocopherol was contin

signs of slipping into light coma, he is at once aroused by a cup of sweet tea and thereby brought round sufficiently to eat the potatoes. The dose of insulin is then reduced slightly the next day. Extra supplies of sugar, and the means of nasal or intravenous interruption, are constantly to hand for use as an emergency measure, but are very seldom required; careful and experienced nursing should do much to obviate their use. This method is almost entirely without danger, and by it as many as 20 patients can be treated in a ward simultaneously if desired. Appetite is often enormously increased; and second and third helpings of potatoes are urged on the patient. A full lunch is provided at 12.15 P.M., and the patients have physical training in the afternoon. So far, no after-shocks have been experienced†, but the patients are not allowed out of the hospital grounds on treatment days except under supervision, and their diet is watched. Treatment is given every day except Sunday; on Saturdays half doses of insulin are given. In successful cases it is continued until physique, appearance, and behaviour return to normal or weight increase stops after an initial steady gain. In practice, the time allowed for each patient is to a certain extent influenced by the number of fresh cases awaiting treatment. Table II records the results obtained in the treatment of 64 patients by this second method. Besides those given in tables I and II, 27 other cases were treated by these methods; 8 of these were schizophrenics; 4 had Cardiazol in addition to insulin; 1 refused to continue treatment; in 14 cases the available records are not entirely complete for various unavoidable reasons; the essential findings in the relevant cases do not differ from those discussed below.

RESULTS

The great difficulty in getting the exhausted neurotic patient to put on weight is only too well known, and some of the large gains in weight shown in the tables are therefore in themselves worthy of record. It may be thought that the mental improvement is entirely secondary to these gains, but it is more probable that they are both symptoms of a common change. It will be noted that the gains in weight in the cases making the best improvement are no greater than the average, and that large gains are sometimes accompanied by little psychiatric benefit, small gains by considerable benefit. It seems likely that other factors, such as the sweating, other autonomic effects, and the general quickening of the metabolism, may also be important.

From the psychiatric point of view, the cases in the first group did not do so well on the whole as those in the second group. There was, however, a difference in the material as well as in the treatment. We soon found that severe cases of depression, especially endogenous in type, and cases with depersonalisation, included in the first group, did not do well, the best results being obtained in men of fairly good personality with anxious, hysterical and depressive symptoms of a reactive type. In these, though long-standing and ingrained neurotic symptoms and tendencies were not relieved in any way, the acute symptoms often diminished.

There were more of these latter cases in the second group. They included men who had broken down in the Flanders retreat or as a result of other severe war stress. Often their condition had passed from the acute to the semi-chronic before they found their way to this unit. Some of them might have been treated with continuous narcosis, but the insulin treatment seemed so much simpler. Their symptoms were often a mixture of depression, anxiety and hysterical features in a reactive setting, and labelling them would be a matter of opinion,

---

† Since this article was written a further 98 cases have been completed. In 4 instances, mild hypoglycæmic symptoms have been observed in the afternoons; they were quickly relieved when sugar was taken by mouth.

An unexpected feature of the investigation was the pronounced effect on the general vitality and emotional tone in 9 of the 25 patients, who said they felt better and were happier and more contented To a large extent the despairing and depressed outlook, engendered by the gravity of their malady, was mitigated, while in 2 cases an actual tendency to euphoria was observed In view of the deterioration in the neuromuscular disorder and consequent increasing incapacity noted in some of these patients, this result was the more surprising It might partly be attributed to the institution of a definite line of treatment in a malady regarded as incurable, but it is also possible that vitamin E may act as a stimulant to general health and give rise to a feeling of well-being in states of depression Judging by our series the body-weight is unaffected by the vitamin

The published reports on the clinical aspects of vitamin-E therapy are as yet so few that Bicknell's statement " that vitamin E appears indeed to be one of the great advances in general medicine of the century " is at least premature, nor has it been justified by the results hitherto recorded From a practical standpoint it seems that vitamin-E therapy is in too early a stage for any definite conclusions to be drawn, and its value in neuromuscular disorders remains speculative

SUMMARY

The experimental and clinical evidence in favour of the application of vitamin-E therapy to neuromuscular disorders, and especially to motor neurone degeneration, is reviewed

A series of 25 cases of motor neurone degeneration is recorded, including bulbar paralysis, progressive muscular atrophy and amyotrophic lateral sclerosis, in which vitamin-E therapy was applied for periods of 5 to 10 months

Vitamin E was given in the form of synthetic α-tocopherol acetate (30 mg daily) or wheat-germ oil capsules equivalent to 18 mg tocopherol daily

Of the 25 cases, only 2 showed definite improvement, a third case reported his condition as improved, and slight improvement in gait was noted in a fourth

Progressive deterioration occurred in all 9 cases of bulbar paralysis

Improved general health and emotional tone were noted in 9 patients

The value of vitamin-E therapy in motor neurone degeneration remains speculative, but in view of the improvement in 2 of our cases it is worthy of further trial

We wish to thank Dr Frederick Prescott for his help in the investigation, Dr Colin Edwards for the notes of two cases, and Messrs Roche Products for supplies of α-tocopherol acetate

MODIFIED INSULIN THERAPY IN WAR NEUROSES

WILLIAM SARGANT,
M B CAMB, M R C P, D P M

NELLIE CRASKE,
M B, B SC MANC

(*From an E M S Neurological Unit*)

PREVIOUS communications from this unit[1] have emphasised that loss of weight and other physical changes have figured prominently in many cases of war neurosis admitted here, especially where there has been severe or protracted stress These changes may occur insidiously, and even where they are considerable the patient often does not look particularly thin or ill on admission Careful inquiry, or the patient's photograph before illness may be necessary to show the extent of the physical alteration Once lost, weight is not easily regained, but it is open to doubt whether a stable psychological recovery can be obtained without restoration of normal physique

Many years ago Weir Mitchell urged the importance of restoration of physique in the treatment of neurotic illness By means of an enormous diet, supplemented by rest and heavy massage to promote sweating and appetite, he bolstered up the neurotic's physical constitution and thereby obtained some remarkable psychological improvements More recently his results were interpreted as being largely due to suggestion, and the essentials of his treatment held of little value This paper reports the results of two modified forms of insulin therapy, the second probably somewhat similar in its effects to the original Weir Mitchell treatment A considerable physical improvement may be obtained, together with amelioration of acute neurotic symptoms But the evidence is against the suggestion that by this means long-standing neurotic tendencies, innate in the personality, are in any way altered There is nothing new in the essentials of this treatment, for many workers have noticed its occasional benefit in psychiatric conditions other than schizophrenia, but such a large series of cases has not previously been reported

TECHNIQUE

For its application to different material, the technique was modified in two stages from that generally used in the treatment of schizophrenia At first, a group of patients with reactive and endogenous depression or anxiety states, who showed loss of weight, were given increasing doses of insulin until light coma supervened The insulin was given intramuscularly at 7 A M, when the patient was fasting, and light coma followed in the third hour afterwards It was interrupted by the nasal administration of 7 oz sugar in tea as soon as it was deep enough for the nasal tube to be passed unnoticed by the patient Interruption by intravenous glucose was also used for convenience, or when hypoglycæmic excitement needed controlling Only a small number of patients could be treated at one time in this way, and though the method eliminated the dangers of prolonged and deep coma it required skilled nursing and constant supervision Large doses of insulin (20–300 units) had to be used, and special precautions, by securing an adequate diet during the rest of the day, were required to prevent the occurrence of after-shocks Table I shows the results obtained in the treatment of 18 cases by this method

As it became necessary to conserve both sugar and insulin, a simpler technique was adopted, which has the considerable advantage that a much larger number of patients can be treated at the same time A smaller dose of insulin (20–100 units) is given fasting at 7 A M, just insufficient to produce a light coma or hypoglycæmic excitement The interruption, at 10 A M, is by giving a cup of tea containing 2 oz of sugar, the rest of the carbohydrate being made up with 12 oz or more of potatoes* The aim is to produce a state of drowsiness for as long as possible between injection and interruption Nasal interruption is no longer necessary If the patient shows so for two days His temperature was 102° F , and pulse rate 120 He had purulent conjunctivitis His lips were swollen and dusky and their inner surfaces were covered with shallow ulcers on which was a greyish adherent false membrane which bled on removal The mucous membrane of the whole mouth, including the gums, inner surfaces of the cheeks, palate, tonsils and faucial pillars were similarly affected The pharynx was reddened and œdematous He could open his mouth only with difficulty and found it very hard to swallow There was no odour to the breath There were a few scattered moist râles and slight blowing breathing at both pulmonary bases A radiogram of the chest was negative Swabs were taken of the mouth lesions and conjunctival secretions Both smears and cultures showed numerous gram-positive encapsulated diplococci which were thought to be pneumococci No other organisms were seen

* The substitution of potatoes for sugar making possible the continuation of treatment on a large scale despite sugar rationing was first suggested by Dr Russell Fraser in a personal communication

Sulphapyridine was given in gramme doses every four hours Within two days the chest symptoms and signs had entirely disappeared but the mouth and eyes showed no improvement, the temperature remained elevated and the patient continued to be very ill Swallowing became more difficult On Aug 18 he developed a pustular rash on his legs but this cleared up rapidly without treatment Unfortunately the pustules were not examined bacteriologically The conjunctivitis improved from this period on and smears were negative on the fifth day Sulphapyridine was continued in gramme doses four hourly until Aug 22 when a total of 36 g had been given During this period his temperature varied from 100 8° to 103 8° F and he remained acutely ill The mouth did not improve although the usual non specific local measures were applied A severe generalised dermatitis developed which was thought to be due to the drug and it was discontinued on Aug 22 There were no facilities available for an estimation of the blood sulphapyridine but the fact that he was very cyanosed suggested that it was well absorbed During this seven day period repeated swabs of the mouth lesions demonstrated a pure culture of the same organism

On Aug 23 his general condition became much worse and resembled the typhoid state He became apathetic, showed extreme prostration and refused anything by mouth His temperature ranged up to 104° F and his pulse became more rapid and thready Hæmoglobin 80% (Sahli), red cells 4,700,000, white cells 5450 Because of the extreme toxæmia it was decided to give him small whole-blood transfusions, and he received 250 c cm of stored whole blood By next morning he was greatly improved and accepted small quantities of food and drink He was given another 250 c cm of stored whole blood next day and this was repeated on the 29th During these days he made a spectacular improvement both in his general condition and his mouth By Sept 5 his stomatitis had cleared up, apart from small scars on his soft palate He was discharged from hospital completely well on Sept 13

CASE 2 —A Canadian subaltern of English origin, aged 21, was admitted on Oct 28, 1940 Four days previously his gums and lips had become dry and sore , they became progressively worse and he felt generally ill On the day of admission he had developed a slight cough and dyspnœa There was a past history of mild periodic asthma and four months before he had had a similar mouth condition accompanied by fever and general malaise At that time he was in another hospital and a diagnosis of " trench mouth " had been made, but there was no record of any bacteriological examination He said that he was not very ill at that time but that his mouth took nearly four weeks to clear up with various local treatments He was severely ill with a temperature of 101 5° F There was acute conjunctivitis with thin purulent secretion His lips were swollen and deeply cyanosed and their inner surfaces had several large shallow ulcers covered with an adherent greyish false membrane which bled on being disturbed The whole mucous membrane of the mouth was similarly affected and the lesions extended back to the soft palate, tonsillar pillars and pharynx He had considerable difficulty in opening his mouth and in swallowing The breath was not fœtid There were a few scattered sibilant rhonchi in both lungs which disappeared a few hours after admission X ray examination of the chest was negative Smears taken from the ulcers and conjunctival exudate showed numerous gram positive encapsulated diplococci and pure cultures of these were obtained No other organisms were found

He was given sulphapyridine, 8 g , in the first twenty four hours and 6 g each day thereafter in divided doses at four hourly intervals , a total of 26 g was given before the drug was discontinued on Oct 31 His condition became steadily worse Temperature reached a maximum of 103° F on the first day and subsided a little, to vary from 99 5° to 101° F He was toxic and drowsy and refused anything by mouth The pulse-rate remained over 110 and by Nov 1 it was considered that he was dangerously ill ; the white cells on this day were 6500

In view of our experience in case 1 and his now desperate condition the patient was given 350 c cm of stored whole blood on Nov 1 (twenty-four hours after the drug had been discontinued) Within a few hours there was a striking change in his whole condition The temperature fell to 99° F and he began to feel and look very much better He was able to swallow comfortably that evening A second transfusion of 250 c cm of stored blood was given next day and a third of like amount on Nov 4 He steadily improved after the first transfusion and by Nov 5 the mouth and eye conditions had almost gone The temperature remained normal after Nov 1 He was discharged completely recovered on Nov 8

CASE 3 —A Canadian medical officer of English origin was admitted on Dec 4, 1940 He had been unwell for several days with slight fever, general malaise and cough On the day of admission he had a severe chill and the other symptoms became aggravated His temperature was 102 2° F , respirations 28 and pulse rate 120 His eyes were slightly reddened and he was intolerant of light The pharynx was injected and there were moist râles and blowing breathing in the left lung base posteriorly and in the right upper lobe A chest radiogram showed some infiltration of the left base and a more definite infiltration of the lower part of the right upper lobe A diagnosis of bilateral bronchopneumonia was made The sputum contained mixed organisms with the pneumococcus predominating Sulphapyridine was given, starting with 2 g , and 1 g every four hours for two days and then gradually reduced until a total dosage of 30 g had been given He slowly improved until his temperature was normal on the fifth day (Dec 9) when the pulmonary signs and symptoms had gone During this time he complained of severe headaches in the frontal area and much photophobia Conjunctivitis was noted from the first day and reached its height on the fifth day There was a thin purulent conjunctival exudate Smears from this exudate showed a few gram positive encapsulated diplococci As his general condition improved he developed ulcerations on his lips, gums, inner sides of the cheeks and under the tongue much like those described in the other cases but not as severe Smears and cultures from these lesions yielded nothing but gram positive encapsulated diplococci Apart from the local discomfort associated with such lesions he felt well and they healed with local treatment only He improved rapidly and by Dec 16 the mouth and eye conditions had disappeared

DISCUSSION

The outstanding feature of these cases was the finding on repeated examinations of pure cultures of a gram-positive encapsulated diplococcus The fact that no other organisms were found on direct smear or culture was most striking Morphologically they could not be distinguished from the pneumococcus and in fact they were considered to be such and the cases were treated accordingly In the two primary cases adequate dosage of sulphapyridine had no beneficial effect , actually, the patients became steadily worse during its administration This observation led us to doubt whether we were really dealing with a true pneumococcus and a further study of our cultures was made Dr C J C Britton, who made a complete study of the organisms at the Bland-Sutton Institute, reported that although they were encapsulated and lance-shaped gram-positive diplococci they could be grown easily on relatively simple media, did not ferment inulin and were not bile-soluble A heat-resistance test was not done The organisms were not agglutinated by any of the pneumococcal typing sera It was thought that they probably belonged to the streptococcus group and were possibly of the fæcalis type This may account for the lack of response to sulphapyridine

Clinically the cases were characterised by the severe local lesions in the mouth and by the extreme general toxæmia Although the first case made a dramatic recovery after small transfusions of pooled blood we doubted whether these had anything to do with the improvement, so that when the second case came in we felt that he should be given full trial on sulphapyridine, The symptoms most benefited by the treatment were those of exhaustion lethargy, loss of appetite, despondency, inability to think clearly, and general feelings of tension Somatic accompaniments of "conditioned" fears, of raids, bombs, aeroplanes and so on might be lessened, but the fears themselves were rarely abolished, they were often too deeply ingrained by the time the patients came for treatment Improvement generally occurred in the first month It was helped by superficial psychotherapy and by such other obviously necessary measures as filling in amnesic gaps The method is of little use against a strong psychological resistance to recovery It has therefore been found most valuable as a means of speeding up rehabilitation in service or civilian cases, before boarding out of the Army or discharge to take up readjusted duties There is no reason to think that even the most successful patients, if again exposed to the stresses causing their breakdown, would not relapse

Psychological factors undoubtedly played a part in the treatment The patients were often exhausted and showed increased suggestibility They were receiving a definite treatment after a long period of therapeutic inactivity, or inefficiently carried out duty Two or three patients in the ward who were doing well influenced the rest Every encouragement was given to them to eat as much as possible with their improved appetite But these things did not explain the whole of the improvement obtained The patients often looked and felt physically better or resembled much more closely the photographs taken of them before their illness And this return to previous physique, if it could be achieved, was taken as the indication for the cessation of this particular form of treatment

CONCLUSIONS

The possible uses of modified forms of insulin treatment for soldiers and civilians suffering from depression and various neurotic reactions have been investigated in a large number of cases Tables showing alterations in weight and symptoms in relation to days of treatment are given for 82 such cases The following general conclusions were arrived at as to the value of such treatment

1 Rapid gains in weight and improvement in appetite may often be obtained in neurotic subjects whose general physique has deteriorated under stress

2 Long-standing neurotic traits, innate in the personality, are not altered The somatic symptoms accompanying recent "conditioned" fears may sometimes be lessened but the fears themselves rarely abolished

3 Generalised neurotic anxiety, and hysterical and depressive symptoms in a reactive setting sometimes improve rapidly The improvement is mainly in the associated symptoms of nervous exhaustion

4 The greatest improvements do not necessarily coincide with the largest gains in weight Other factors seem to play a part

5 Severe cases of depression, especially of the endogenous type, were less helped by the methods used In other cases, not reported here, convulsion therapy or continuous narcosis has been a useful alternative treatment

6 The treatment is ineffective against strong psychological resistance to recovery When used, it should be in conjunction with other established methods of treatment for neurosis and with adjustment of environment

7 In practice, its main value will be for speeding up normal processes of recovery in patients to be boarded out of the Army, fit to do civilian work, or before they are returned to readjusted duties

L P LANSDOWN
M D MANITOBA

MAJORS R C A M C

(*From No 5 Canadian General Hospital, Overseas*)

WE have recently seen three cases of acute ulcerative stomatitis or angina which differed materially from the better known clinical types Their severity, the peculiar bacteriological findings and the results of treatment led us to think that they should be reported They were almost identical in their clinical course and were characterised by widespread ulcerative lesions of the lips, buccal cavity and pharynx with an associated mild purulent conjunctivitis All the patients were acutely ill and two of them showed alarming prostration Repeated swabs from the ulcerated areas and the conjunctival secretion in all cases yielded pure smears and cultures of an encapsulated gram-positive diplococcu This organism resembled the pneumococcus morphologically, but subsequent careful investigation showed that it had none of the cultural or serological characteristics of the pneumococcus group Repeated swabs of the various lesions always yielded pure smears and cultures of the same organism throughout the acute phase of the illness

Chalier and Ledu (1939) report cases which they call acute pneumococcal angina and from which they recovered pure smears and cultures of the pneumococcus They suggest that the condition is common but describe only a few of their own cases They say that many cases with membranous lesions of the tonsils and pharynx which are suspected of being diphtheritic yield smears and cultures of pneumococci, and that most of these cases are mild and clear up rapidly with local measures However, they report some further cases which were very severe and which were associated with much general toxæmia In these the usual methods of treatment, including antipneumococcal sera (type not specified), were ineffective They treated five cases with sterilised beef bile applied locally with apparent success All their reported cases were febrile and toxic and showed œdema and shallow ulceration associated with an adherent membranous exudate involving the lips, gums, insides of the cheeks, tongue, palate, tonsils and pharynx Although they state that pure cultures of pneumococci were obtained in all cases they give no evidence that the identification of the organisms was based on anything other than their appearance

Schmidt La Baume and Otto (1933) quote three cases These all had lobar pneumonia with a concurrent ulcerative and pseudomembranous stomatitis due to organisms said to be pneumococci One of these cases developed a rash from the lesions of which supposed pneumococci were recovered They also describe a fourth case which had pneumonia, stomatitis and a pustular exanthem from which "pneumococci" were recovered in pure culture Again identification of the organisms was incomplete and appeared to be only morphological

It seems that cases of acute ulcerative stomatitis or angina do occur in which an encapsulated diplococcus is the only organism found Such cases may arise as primary conditions resembling diphtheria, or may be a complication of pneumonia In all the reported cases there was moderate or high fever accompanied by severe toxæmia The local condition is characterised by swelling and cyanosis of the mucous membranes of the lips, gums, buccal cavity, palate, fauces, tonsils, tongue and pharynx There is widespread superficial ulceration with production of an exudate best described as a false membrane which is adherent and bleeds easily on being disturbed The membrane appears as glistening greyish white patches of varying size which become confluent in the more severe cases We have to report two similar primary cases and a third secondary to pneumonia

CASE-HISTORIES

CASE 1 —A French Canadian soldier, aged 28, was admitted to hospital on Aug 15, 1940 He was acutely ill and had been

observations that the serum-calcium is normal in myxœdema, and that adequate thyroid therapy causes the serum-calcium to fall below normal

Phosphorus.—The mean inorganic phosphorus in the serum in untreated myxœdema is slightly raised above the normal mean but the difference is not significant, for $P > 0.4$ Thyroid feeding caused the mean inorganic phosphorus to rise from 3.93 to 4.22 mg per 100 c cm, and this rise is probably significant, for $P = 0.05$ This assumption is supported by the significant difference in the mean inorganic phosphorus level of treated myxœdema and normal controls, for $P < 0.01$ These observations show that in myxœdema the serum inorganic phosphorus is normal and that thyroid feeding causes the phosphorus to rise These findings were not anticipated, with a fall in the serum-calcium I expected a corresponding fall in the inorganic phosphorus similar to that found in thyrotoxicosis A possible explanation is that given by Albright and others (1931), who described a variation in the serum-calcium and inorganic phosphorus ratio such that their product remained roughly constant If this is so then this relationship is not present in thyrotoxicosis, where both the serum-calcium

and this was done He became progressively worse and on the fifth day the drug was discontinued because it was clearly not benefiting him and was probably making him worse Next day his prostration was so great that his life seemed in danger We now started transfusions of pooled blood and again spectacular improvement set in within a few hours We appreciate that pooled stored blood has little, if any, antibody or complement but the fact remains that immediate improvement followed its use in two successive cases

King (1940) has drawn attention to the possibility of a deficiency of the pellagra-preventing factor (nicotinic acid) in cases of " trench mouth " and Vincent's disease Our patients may also have suffered from some deficiency although their stomatitis was associated with the diplococcus described instead of the usual Vincent's organisms If so, the stored whole blood may have supplemented the deficiency and thereby led to the rapid recovery With this idea in mind we wanted to use nicotinic acid in the second case but supplies of the drug could not be obtained in time

The general appearance of the mouths of all three of our cases was compatible with Vincent's disease, but there was no unpleasant odour to the breath and of course the bacteriological examination confirmed the absence of that type of infection It seems probable that in many of the mild cases of stomatitis which are diagnosed as Vincent's infection without a bacteriological examination such examination would reveal an infection with a similar organism to that we have described, or perhaps others King's thesis—that ulceromembranous infections of the mouth with Vincent's organisms are associated with a defective cell metabolism due to a deficiency of part of the vitamin B. complex—may also apply to infections with other organisms

The cases here reported could have been classified as pneumococcal stomatitis if full bacteriological study had not shown that the organisms were not pneumococci All cases of buccal ulceration seen here are now being examined bacteriologically to determine the frequency of this type of infection

SUMMARY

Three unusual cases of ulcerative stomatitis are reported in which repeated bacteriological examination showed pure smears and cultures of a gram positive encapsulated diplococcus which lacked many of the cultural, biological and serological properties of the pneumococcus A diagnosis of pneumococcal stomatitis should therefore be made with caution

The disease did not respond to adequate sulphapyridine therapy but transfusions of pooled whole blood seemed to act as a specific It is suggested that infection of the mouth with organisms other than Vincent's may be associated with a deficiency of nicotinic acid

We are indebted to Colonel Leonard Colebrook, Dr C J C Britton and Major Charles Moore for their advice and assistance, and to the Director of Medical Services, Canadian Army (Overseas), for permission to publish this report

CALCIUM AND PHOSPHORUS STUDIES IN MYXŒDEMA*

J Douglas Robertson, M D, D Sc St And, D P H

On a low daily intake of calcium, such as 0 1 g, the normal person steadily loses about 0 25 g a day, chiefly in the fæces but also in the urine In thyrotoxicosis, on a similar intake the loss is much greater This was clearly demonstrated in 1910 by Towles, later by Aub and his colleagues (1929), and more recently in a study of 33 cases by Beaumont, Dodds and Robertson (1940) It has further been shown by the last two groups of workers that successful subtotal thyroidectomy was accompanied by a return of the calcium balance to normal limits A natural corollary to these observations would be the demonstration that in myxœdema the calcium output was diminished and that it rose to normal after adequate thyroid therapy Of 5 cases of myxœdema reported by Aub and his colleagues (1929) only 2 showed an increased calcium loss after thyroid feeding, in the other 3 the calcium loss was actually diminished

In the present paper the calcium and phosphorus metabolism has been studied in 3 cases of myxœdema before and after thyroid feeding Observations were also carried out on the serum calcium, inorganic phosphorus and phosphatase to determine whether these substances were altered in myxœdema and whether thyroid feeding changed their concentrations

CALCIUM AND PHOSPHORUS METABOLISM

In table I the results of the calcium and phosphorus lances in the 3 cases of myxœdema are given In bles II, III and IV a more detailed analysis of the calcium d phosphorus metabolisms of these cases has been esented

In view of the variations in the calcium intake the lcium balance was used for comparison The mean gative calcium balance in myxœdema per three days as 4 78 mg per kg body-weight, as compared with 58 mg in my study of 9 normals reported in the first per of this series On adequate thyroid medication uring which the basal metabolism rose from − 41 to 5) the mean negative calcium balance increased to 79 mg Thyroid feeding produced an increased calcium ss in all cases, greatest in the youngest subject In treated myxœdema the body stored phosphorus per three days at the rate of 4 21 mg per kg of body-weight Thyroid feeding changed this gain into a loss of 9 88 mg comparable with the negative balance in normal people of 10 54 mg per kg Table IV shows the calcium and phosphorus balance in a case (FB) of myxœdema where the output of these minerals in the urine and fæces was measured separately

The reduction in calcium output was greater in the urine than the fæces, the calcinuria amounting to 14% of the total calcium output as compared with the normal of 24% The calcium output rose after thyroid feeding, the increase taking place chiefly in the urine The reduction in the phosphorus output was also chiefly in the urine, the phosphaturia amounting to 55% of the total phosphorus output as compared with the normal of 70% After thyroid feeding there was a decided increase in the urinary output of phosphorus and at the same time a fall in the output of phosphorus in the fæces

BLOOD-SERUM STUDIES

Calcium—The blood-serum findings are set out in tables V and VI The mean serum-calcium in untreated myxœdema is slightly raised above the normal mean but the difference is not significant, according to Fisher's P test (1938), for $P = 0\ 3$ Thyroid feeding brought about a fall in the mean serum calcium from 10 51 to 9 85 mg per 100 c cm Statistically this difference is significant, for $P < 0\ 01$ There is also a significant difference in the levels of the serum-calcium in normal people and in the cases of myxœdema treated with thyroid, for $P < 0\ 01$ It seems, therefore, from these

observations that the serum-calcium is normal in myxœdema, and that adequate thyroid therapy causes the serum-calcium to fall below normal

Phosphorus —The mean inorganic phosphorus in the serum in untreated myxœdema is slightly raised above the normal mean but the difference is not significant, for $P > 0\ 4$ Thyroid feeding caused the mean inorganic phosphorus to rise from 3 93 to 4 22 mg per 100 c cm , and this rise is probably significant, for $P = 0\ 05$ This assumption is supported by the significant difference in the mean inorganic phosphorus level of treated myxœdema and normal controls, for $P < 0\ 01$ These observations show that in myxœdema the serum inorganic phosphorus is normal and that thyroid feeding causes the phosphorus to rise These findings were not anticipated , with a fall in the serum-calcium I expected a corresponding fall in the inorganic phosphorus similar to that found in thyrotoxicosis A possible explanation is that given by Albright and others (1931), who described a variation in the serum-calcium and inorganic phosphorus ratio such that their product remained roughly constant If this is so then this relationship is not present in thyrotoxicosis, where both the serum-calcium

and inorganic phosphorus were found to be below normal

Phosphatase—The mean serum-phosphatase in untreated myxœdema is diminished below the normal mean and there is a significant difference, for $P > 0\ 02$ In comparing the serum phosphatase before and after thyroid feeding it will be noted that the standard deviations are high in proportion to the difference in the respective means In view of the small number of cases of myxœdema investigated it is unlikely that a significant difference could be demonstrated before and after thyroid medication and this in fact was so, for $P = 0\ 1$ If however the treated or untreated cases of myxœdema are compared with the 60 normal controls in the first paper in this series it is found that a significant difference exists between the untreated myxœdema and the controls and that there is no significant difference between the treated myxœdema and the controls It seems justifiable to conclude that the serum-phosphatase is diminished in myxœdema and that thyroid feeding raises it to normal

SUMMARY

In 3 cases of myxœdema the negative calcium balance was found to average 4 78 mg per kg of body-weight per three-day period, compared with the normal of 7 58 mg The diminution in output chiefly affected the urine

The phosphorus output was diminished, so that a positive balance was produced Per three day period there was a retention of phosphorus amounting to 4 21 mg per kg body-weight, compared with a loss, or negative balance, in normal subjects of 10 51 mg The diminution chiefly affected the urine

Examination of the blood in myxœdema showed that the calcium and inorganic phosphorus of the serum are normal but that serum-phosphatase is diminished

Adequate thyroid medication, resulting in a return of the heat output to normal, produced the following changes in the calcium and phosphorus metabolism The negative calcium balance per three-day period rose from 4 78 mg per kg to 9 79 mg, the increased output taking place almost entirely in the urine There was an increased phosphorus output, changing the balance in three days from a positive one of 4 21 mg per kg to a negative one of 9 88 mg, the increase in output taking place only in the urine and being accompanied by a fall in the fæcal output of phosphorus The immediate effects on the blood-serum were that the serum calcium fell below normal limits, the inorganic phosphorus rose above normal in proportion to the fallen serum calcium, and the diminished serum-phosphatase rose to normal limits

Reviews of Books

Old-age Pensions

An historical and critical study By SIR ARNOLD WILSON, M P, and G S MACKAY London Humphrey Milford, Oxford University Press Pp 229 16*s*

THIS is the first full description and examination of one of the most important social developments of our time It should be of great interest and use to every thoughtful citizen and particularly to our profession It is an impartial and lucid account of the steps which have produced our British system In the historical section the authors bring out many facts which will be new to the general reader They show that the duty of making provision for old age and dependency is enjoined in many religious systems Legislation of the time of Henry VIII assumed that the poor will be supported by voluntary alms, but Elizabeth prescribed compulsion In the reign of Charles I, attempts were made to establish an elaborate system, far in advance of his times, but the Puritans strongly discouraged anything which tended to diminish personal thrift, an attitude which was closely followed by the friendly societies later, who were the sternest opponents of state assistance This is brought out in the description of the efforts of Joseph Chamberlain, who became in the 1890's the great champion of old-age pensions He scornfully said in Parliament "some economists expect from the poor a virtue which we do not find in ourselves" But his efforts to secure legislation were defeated, and he had to acknowledge that "the vested interest in voluntary thrift is overwhelmingly strong" It was Mr Lloyd George who in 1908 put non-contributory pensions on the Statute Book, and the only opposition came from a small body of "hard-boiled" individualists The book describes the various steps by which the original non-contributory pension has been raised from 5*s* to 10*s* a week, and the maximum income which will attract the full pension from £31 10*s* a year to £49 17*s* 6*d* The authors point out that in July, 1939, this 10*s* had the same value as 16*s* had when the earlier rate was fixed The same full particulars are given of the inception in 1925 and growth since of the contributory schemes, which give to all "insured persons" the right to a pension at 65 There are chapters on the adaptation of the system to war conditions and on old-age pensions in other countries, from which it appears that we were the last country but two out of the twenty-five tabulated as having obligatory schemes, being followed in 1927 by Cuba and Russia In a concluding chapter we are told of the Labour Party's plea in July, 1939 for a rise in the pension to £1 a week, with 35*s* for a married couple, followed by the reminder by Neville Chamberlain that the cost of the non-contributory pensions all came out of the general taxpayer and 60% of the contributory, and that the cost to the taxpayer had risen from 8¼ millions in 1909 to over 69 millions in 1939 The means test which is used in dealing with the supplementary pensions of 1940 is considered by the authors as "not a permanency but useful as a quick remedy for a war-time difficulty" They remind us that "all classes may have to revise their ideas as to what is a tolerable part of their income for the state to demand in peace-time, whether as taxes or contributions"

In his foreword Sir George Schuster deals briefly with general principles, and in a long and interesting preface Mr W B Reddaway discusses the vexed question of decreasing fertility

Applied X Rays

(3rd ed) By GEORGE L CLARK, D Sc London McGraw Hill Publishing Co Pp 674 42*s*

MUCH of this book is inevitably related to non medical sciences The study of the physics of X rays crosses the path of medicine little more than does the science of visible light, but though Professor Clark of Illinois gives relatively little space to medicine the book is none the less of considerable interest to those associated with medical radiology The chapter on the biological effects of X radiation is well set out and up to date, and gives the reader a clear idea of the theories of the actions of X rays on living cells The second part, which occupies about two-thirds of the volume, deals with the X-ray analysis of the ultimate structure of materials It makes fascinating reading and illustrates how X rays have revolutionised chemistry in the conception of the structure of solids Only a generation ago crystallography was a very small branch of chemistry, but since the work of the Braggs X-ray analysis has made it one of the largest and foremost branches

Annual Review of Physiology

Vol III Edited by J M LUCK and V E HALL, Stanford University California American Physiological Society and Annual Reviews Inc Pp 784 $5

THERE are 28 articles by 31 authors in this book which is bigger than volume II, and—in its average level of reviewing—better A good review should give views as well as news, and there is a welcome increase in the number of contributions in which recent work is evaluated as well as recorded This trend is well worth an increase in size The articles on histamine and anaphylaxis (Feldberg), bacterial chemotherapy (E K Marshall) and the autonomic nervous system (D Sheehan) are probably those of most clinical interest, though few are devoid of clinical significance in one respect or another

AMERICAN DOCTORS FOR BRITAIN—The response to the request made by the British Red Cross for 1000 American doctors has not so far been large By the middle of July, 18 doctors were about to leave, and another 56 were soon to follow The chance that the United States may herself be entering the war is said to b

VITAMIN E FALLS FROM GRACE

VITAMIN therapy is passing into relative disrepute ecause one after another of the enthusiastic claims made are being disproved The sequence of events s often the same A biochemist feeds lower animals n a purified diet and induces pathological changes hat are later prevented or cured by the addition of a oncentrate or a pure chemical substance A new vitamin has been found The discoverer perhaps uggests human diseases that may be benefited by such therapy because he believes them, often wrongly, o be analogous to the pathological condition in his animals or the clinician, legitimately encouraged by its manufacturers, tries the new panacea on a few of his patients who loyally say they feel better Before the series of cases and controls are adequate the results are published, and other clinicians hasten to join what Walshe has aptly termed the vitamin band-waggon It remains for more cautious workers to investigate the claim laboriously and publish their negative results This sorry story cannot yet be told about vitamin E, but the fires of enthusiasm already burn less brightly

We are indebted to H M Evans for the discovery and most of the chemistry of vitamin E, and he was the first to show[1] that suckling rats developed paralysis if their mothers were kept on a diet deficient in this factor The subsequent work on animals, which we reviewed last year[2] culminated in the suggestion of Einarson and Ringsted[3] that amyotrophic lateral sclerosis and tabes dorsalis might be due to deficiency of the vitamin Clinically, the hypothesis was first put to the test independently by Bicknell[4] and Wechsler The former treated 18 cases of muscular dystrophy with 1 oz of dried fresh wheat germ daily, and noted improvement in all except 6 of the 11 cases that he classified as advanced He also noted improvement in 2 cases of amyotrophic lateral sclerosis and a single case of amyotonia congenita, although he had faith that vitamin E would be of value in tabes, neither of his 2 advanced cases improved Bicknell believed that the muscular dystrophies, and most probably amyotrophic lateral sclerosis, were deficiency diseases and curable Wechsler[5] treated 2 cases of amyotrophic lateral sclerosis with the synthetic ester of the vitamin (tocopherol acetate, 9 or 18 mg daily), one case completely recovered and the other was much improved, but 3 advanced cases did not improve He believed that vitamin B may aid vitamin E in treatment, and gave his later patients B complex as well as E Later[6] he reported varying success in 11 of 20 cases of amyotrophic lateral sclerosis that were "carefully observed and consistently treated", some 30 cases in all were treated These patients received daily 30–200 mg of α-tocopherol acetate, 2 teaspoonfuls of wheat-germ oil, a diet rich in vitamin E, with bile salts and the whole vitamin-B complex More recently,[7] he presented at a meeting 7 cases successfully treated, and could show 4 or 5 others who had partially improved But he could cite at least 25 patients who had not improved at all with treatment, and assured the meeting that there were at least three and possibly four kinds of amyotrophic lateral sclerosis, of which only one (representing a third or a quarter of all cases) would respond to vitamin E Stone[8] used wheat-germ oil, 2 ml a day by mouth, and yeast tablets in the treatment of 5 cases of muscular dystrophy, one patient with muscular atrophy after anterior poliomyelitis, and one with muscular atrophy after multiple neuritis, all improved, particularly when the vitamin-B complex was added A pure member of the B complex was first used by Antopol and Schotland,[9] who were encouraged by their work on rats to try synthetic vitamin B_6 in the treatment of 6 patients with pseudohypertrophic muscular dystrophy Considerable improvement was noted in all, but none was cured and one relapsed and became worse despite intensive therapy This work has not been confirmed[10] Spies and his colleagues have made optimistic claims for both vitamins B_6 and E Synthetic α-tocopherol benefited occasional cases of amyotrophic lateral sclerosis[11], and injection of 500 mg relieved "neuromuscular symptoms, roaring sensations in the ears, anorexia, and insomnia of selected persons with malnutrition", 4 people given B_6 became less irritable, less nervous, less weak and less awkward in walking,[12] but this also has not been confirmed[13], cases of pernicious anæmia in relapse showed a reticulocytosis[14], improvement was noted in amyotrophic lateral sclerosis,[15] and also in cases of idiopathic epilepsy myasthenia gravis, and postencephalitic parkinsonism[16] (Jolliffe[17] found improvement also in non-postencephalitic parkinsonism) Thus the vitamin band-waggon rumbles along

Others have not been so successful with vitamins E or B_6 or both together At the Mayo Clinic[18] synthetic α-tocopherol combined with wheat-germ oil produced no therapeutic benefit in 6 cases of amyotrophic lateral sclerosis, 4 of progressive muscular atrophy and 8 of progressive muscular dystrophy At the Boston City Hospital[19] 8 cases of motor-neurone degeneration, a case of Erb-Landouzy scapulohumeral and one of Charcot-Marie-Tooth muscular dystrophy, a case of pseudohypertrophic muscular dystrophy and one of amyotonia congenita were treated with an excellent diet, cod-liver oil vitamin-B complex syrup, vitamins B_1 and B_6 and liver extract intramuscularly, wheat-germ oil and α-tocopherol intramuscularly In all 12 patients there was either no change or the disease progressed, in 2 definite and early cases of amyotrophic lateral sclerosis there was unabating and rapid progression From two New York hospitals equally negative results were reported simultaneously Denker and Scheinman[20] treated 15 cases of amyotrophic lateral sclerosis with large doses of α-tocopherol, both by mouth and by injection and 4 of these with massive doses of vitamin B_6, no therapeutic results of any value were observed Ferrebee and others[21] treated 13 cases of pseudohypertrophic muscular dystrophy and 13 of motor-neurone degeneration with wheat germ, Tocopherex, vitamin B_6, and α-tocopherol both by mouth and by injection, and failed in every case to influence the course of the disease, all the 6 cases of amyotrophic lateral sclerosis, which were treated for more than five months, became considerably worse In this issue we publish Dr Worster-Drought's series of 25 cases of motor-neurone disease treated for five to ten months with α-tocopherol acetate or wheat-germ oil, only 2 or possibly 3 improved neurologically, all being patients with amyotrophic lateral sclerosis who received α-tocopherol only

A year ago we suggested [2] that it would be an advantage in future work if untreated controls were observed, and if analyses of creatine-creatinine excretine were carried out as a more definite indication of the extent of concurrent muscular wastage than was provided by merely subjective impressions Ferrebee and his colleagues noted no change in the creatinuria and creatine tolerances of 2 cases of pseudohypertrophic muscular dystrophy treated orally and parenterally with α-tocopherol In Madrid, Vivanco [22] treated 4 cases of progressive muscular atrophy, 1 of dystrophia myotonica and 3 of amyotrophic lateral sclerosis for two months with 2 ml of wheat-germ oil and 40 g of dried brewer's yeast daily The only patients who did not improve were one with progressive muscular dystrophy and 2 with amyotrophic lateral sclerosis The excretion of creatine and creatinine was observed before and during treatment, and the former not only failed to fall but actually rose in all cases (except one in which it was zero throughout and a second in which no estimations were made), thereby pointing to a true deterioration Recently Fitzgerald and McArdle [23] have carried out a full and careful investigation of 20 cases of motor-neurone disease and muscular dystrophy Bemax, Viteolin and synthetic α-tocopherol acetate and vitamin B_6 were administered in large doses In each case there was no significant clinical improvement, and no biochemical evidence of improvement judged by the daily excretion of creatine and creatinine

It is difficult to reconcile these conflicting claims Amyotrophic lateral sclerosis is a disease without remissions, and Wechsler [5] claimed that in one of his patients the weakness returned twice when treatment was stopped "This is almost absolute proof of the efficacy of the treatment," he said, but it may be objected that the patient knew when his treatment was stopped and started Fitzgerald and McArdle noted dramatic subjective improvement in one case within an hour of the intravenous injection of vitamin B_6, but equally dramatic improvement followed the injection of saline next day Yet Antopol and Schotland [9] claimed that one of their patients, who was getting progressively worse, improved with vitamin-B_6 therapy, partially relapsed when saline was substituted, and improved again when B_6 was injected once more Doyle and Merritt,[19] however, were struck by the variations in the natural course of motor-neurone disease In one of their cases the rapid onset and progression during the early part of the illness was followed by years of slow advancement Such variations might lead to a false impression of the value of therapy, and might explain the much smaller percentage of successfully treated cases that Wechsler now claims For this reason biochemical evidence of improvement is especially valuable In rats [24] and rabbits [10] with nutritional muscular dystrophy there is an abnormally large excretion of creatine which falls steeply when α-tocopherol is given In man also the amount of creatine in the urine (on a creatine-free diet) depends on the amount of improperly functioning muscle, and its provides a convenient biochemical method of asse therapy All three groups of workers who have this criterion have found vitamin E and vitamin completely valueless in human muscular dystrop and motor-neurone disease In the earlier papers seemed that those who used synthetic vitamin E vitamin B_6 were unsuccessful, whereas those wh used whole wheat germ, or the oil combined wit vitamin-B complex, obtained encouraging And since it has been maintained,[25] though probab wrongly,[10 26 27] that a water-soluble member of vitamin-B complex (perhaps the doubtful vit B_4) is necessary in addition to vitamin E for the of nutritional muscular dystrophy in animals, seemed that the solution lay in the use of vitamin preparations—in fact, vitamin B_1 itself been claimed [28] to cure nutritional muscular dyst produced in animals by a diet deficient in vitamin E This impression of the advantage of crude over synthetic vitamins proves on closer analysis to be questionable, for some of the most unsuccessful workers [18] used the most extensive therapy That there is something behind all this no-one can doubt What it is may yet emerge from further studies, in which untreated controls must also be observed and biochemical tests employed where possible as an adjunct to critical clinical observation

GETTING THE BEST FROM GOOD TOOLS

WE have been told that in time of national need we must think of ourselves as links in a chain or cogs in a machine These similes should help us to remember that chains, cogs and other items of machinery are subject to wear and tear The good workman looks after his tools because he knows his care will be repaid in time saved at work A saw that needs resetting is a jibbing delaying tool, and a man that needs a holiday is equally unhandy During the last war VERNON and his colleagues made a reliable assessment of optimum conditions of work They collected evidence on the effects of hours of work, arrangement of work periods, lighting, rest pauses and the like, and most of this knowledge had been applied in industry before the armistice Since 1919 the Industrial Health Research Board has collected more information on these and related subjects which should have safeguarded us against the stupid and extravagant mistakes made in the early stages of the last war It was worse than disappointing to see, en this war broke out an impulsive scamper to rease production by simple increase of the number hours worked The knowledge so carefully accumulated during the last twenty-five years was immediıly discarded. The facts however, remained the ne and it soon became clear that the initial output hieved by this misguided burst of energy could not maintained Absenteeism and sickness-rates eased as scientists knew they must and producon suffered with the producers Some of the worst uses were remedied but though members of the vernment, from the Prime Minister downwards ve stated the principle often enough there is still general realisation that only by keeping demands the workers within physiological limits can output maintained at its maximum level.

We have an outstanding opportunity at present assess the needs of workers, especially those whose ities make an unusually heavy demand on them, and formulate scientific procedures which would help us place men in jobs appropriate to their capacity. nly a small proportion of men boarded out of the rmy find suitable work too often they are left to fend or themselves to gravitate into any job they are able get, or to sink into a state of chronic incapacity hich not only destroys their contribution to the ational output but may at last bring them into the anks of an army of misfits similar to that left by the ast war Lord BEAVERBROOK speaking of Watt s work on radiolocation said · "Technical developments make progress in war which sometimes outstrips all that has gone before It is the scientist who will heal our wounds It is the scientist who will protect us against the loss of our life-blood ' Perhaps , but science can do nothing if the knowledge it makes available is neglected

Recently the zeal of miners has been questioned often by people without knowledge of the risk and strain of coal-mining The accident-rate among miners is three times as great as among workers in other industries Their work is heavy and carried out in distorted postures, under working conditions which inevitably fall short of those demanded and enforced in industries above ground Men in the insured population as a whole are incapacitated by sickness for an average of 8 7 days a year, in miners the corresponding period is 18 days, and many incapacitating conditions—septic and inflammatory skin conditions, rheumatic disease, anæmia and gastritis—are two or three times as common among miners as among the general population Fatal accidents at the coal face increased from 783 in 1939 to 910 in 1940 a similar rise was observed in 1914–18. Work carrying such hazards deserves a specially good health service , and it may even be that in order to maintain his full efficiency the miner must have special concessions over and above his 8 oz of cheese when foodstuffs and clothing are being apportioned. The Minister of Labour has already agreed that it would probably be better to allow the present miners 2*s* 6*d* worth of meat a week than take back another 10,000 men If further investigation shows that rationing concessions to miners are justified, no administrative difficulties should be allowed to stand in the way Colonel WALTER ELLIOT has suggested[1] that feeding on the spot in works and canteens is one way of ensuring that supplementary rations get to those who most need them It should not be an impossible piece of research to determine the quantities and types of foodstuffs needed

NEW WORK ON CARCINOGENESIS

SOME three years ago DODDS GOLBERG, LAWSON and ROBINSON,[1] in an account of the œstrogenic activity of certain derivatives of diphenylethane and stilbene drew attention to the structural resemblance between the molecules of diethylstilbœstrol (I) and œstrone (II) The comparison indicated that by ring closure there could be obtained from diethylstilbœstrol a condensed carbon ring compound similar to œstrone on the one hand and to chrysene on the other Since all the known carcinogenic hydrocarbons possess this polycyclic aromatic structure, it was decided to ascertain to what extent the condensed rings of the carcinogens might be disrupted without a complete loss of the characteristic biological activity DODDS LAWSON and WILLIAMS[2] have now reported that two tumours have developed in mice which had been painted for considerable periods with a solution in benzene of α-ethyl-β-*sec*-butylstilbene (III) This possesses a skeletal resemblance to 3 4-benzpyrene (IV) and 1 2-dimethylchrysene (V) the carcinogenic activity of which had previously been described by COOK and others[3] The tumours obtained by DODDS and his collaborators were unusual in that both were spindle-celled, one being a spindle-celled epithelioma and the second apparently a sarcoma—that is they were of histological types not commonly encounte after the application of carcinogenic agents to skin in mice It should also be noted that connective-tissue tumour arose not in the pa area but subcutaneously about 2 cm away. there can be no doubt that these tumours were nant and although attempts to transplant th failed fragments of the sarcoma were suc grafted in stock mice The yield of tumours doubtedly low, and the latent period of moderately long, since the first tumour dev one of a group of seven mice after 1 mont and the second in one of a gr 15 months . these groups we two series of twenty-five adult which the experiment was desirable that the experimen and this is being done If t this will be the first des associated with a hydro condensed structure

of 25 cases of motor-neurone disease treated for five to ten months with α-tocopherol acetate or wheat-germ oil, only 2 or possibly 3 improved neurologically, all being patients with amyotrophic lateral sclerosis who received α-tocopherol only

A year ago we suggested[2] that it would be an advantage in future work if untreated controls were observed, and if analyses of creatine-creatinine excretine were carried out as a more definite indication of the extent of concurrent muscular wastage than was provided by merely subjective impressions Ferrebee and his colleagues noted no change in the creatinuria and creatine tolerances of 2 cases of pseudohypertrophic muscular dystrophy treated orally and parenterally with α-tocopherol In Madrid, Vivanco[22] treated 4 cases of progressive muscular atrophy, 1 of dystrophia myotonica and 3 of amyotrophic lateral sclerosis for two months with 2 ml of wheat-germ oil and 40 g of dried brewer's yeast daily The only patients who did not improve were one with progressive muscular dystrophy and 2 with amyotrophic lateral sclerosis The excretion of creatine and creatinine was observed before and during treatment, and the former not only failed to fall but actually rose in all cases (except one in which it was zero throughout and a second in which no estimations were made), thereby pointing to a true deterioration Recently Fitzgerald and McArdle[23] have carried out a full and careful investigation of 20 cases of motor-neurone disease and muscular dystrophy Bemax, Viteolin and synthetic α-tocopherol acetate and vitamin B_6 were administered in large doses In each case there was no significant clinical improvement, and no biochemical evidence of improvement judged by the daily excretion of creatine and creatinine

It is difficult to reconcile these conflicting claims Amyotrophic lateral sclerosis is a disease without remissions, and Wechsler[5] claimed that in one of his patients the weakness returned twice when treatment was stopped "This is almost absolute proof of the efficacy of the treatment," he said, but it may be objected that the patient knew when his treatment was stopped and started Fitzgerald and McArdle noted dramatic subjective improvement in one case within an hour of the intravenous injection of vitamin B_6, but equally dramatic improvement followed the injection of saline next day Yet Antopol and Schotland[9] claimed that one of their patients, who was getting progressively worse, improved with vitamin-B_6 therapy, partially relapsed when saline was substituted, and improved again when B_6 was injected once more Doyle and Merritt,[19] however, were struck by the variations in the natural course of motor-neurone disease In one of their cases the rapid onset and progression during the early part of the illness was followed by years of slow advancement Such variations might lead to a false impression of the value of therapy, and might explain the much smaller percentage of successfully treated cases that Wechsler now claims For this reason biochemical evidence of improvement is especially valuable In rats[24] and rabbits[10] with nutritional muscular dystrophy there is an abnormally large excretion of creatine which falls steeply when α-tocopherol is given In man also the amount of creatine in the urine (on a creatine-free diet) depends on the amount of improperly functioning muscle, and its estimation provides a convenient biochemical method of assessing therapy All three groups of workers who have used this criterion have found vitamin E and vitamin B_6 completely valueless in human muscular dystrophies and motor-neurone disease In the earlier papers it seemed that those who used synthetic vitamin E or vitamin B_6 were unsuccessful, whereas those who used whole wheat germ, or the oil combined with the vitamin-B complex, obtained encouraging results And since it has been maintained,[25] though probably wrongly,[10 26 27] that a water-soluble member of the vitamin-B complex (perhaps the doubtful vitamin B_4) is necessary in addition to vitamin E for the cure of nutritional muscular dystrophy in animals, it seemed that the solution lay in the use of purified vitamin preparations—in fact, vitamin B_1 itself has been claimed[28] to cure nutritional muscular dystrophy produced in animals by a diet deficient in vitamin E This impression of the advantage of crude over synthetic vitamins proves on closer analysis to be questionable, for some of the most unsuccessful workers[18] used the most extensive therapy That there is something behind all this no-one can doubt What it is may yet emerge from further studies, in which untreated controls must also be observed and biochemical tests employed where possible as an adjunct to critical clinical observation

GETTING THE BEST FROM GOOD TOOLS

We have been told that in time of national need we must think of ourselves as links in a chain or cogs in a machine These similes should help us to remember that chains, cogs and other items of machinery are subject to wear and tear The good workman looks after his tools because he knows his care will be repaid in time saved at work A saw that needs resetting is a jibbing delaying tool, and a man that needs a holiday is equally unhandy During the last war **Vernon** and his colleagues made a reliable assessment of optimum conditions of work They collected evidence on the effects of hours of work, arrangement of work periods, lighting, rest pauses and the like, and most of this knowledge had been applied in industry before the armistice Since 1919 the Industrial Health Research Board has collected more information on these and related subjects which should have safeguarded us against the stupid and extravagant mistakes made in the early stages of the last war It was worse than disappointing to see, when this war broke out, an impulsive scamper to increase production by simple increase of the number of hours worked The knowledge so carefully accumulated during the last twenty-five years was immediately discarded The facts, however, remained the same, and it soon became clear that the initial output achieved by this misguided burst of energy could not be maintained Absenteeism and sickness-rates increased as scientists knew they must, and production suffered with the producers Some of the worst abuses were remedied but though members of the Government, from the Prime Minister downwards have stated the principle often enough, there is still no general realisation that only by keeping demands on the workers within physiological limits can output be maintained at its maximum level

We have an outstanding opportunity at present to assess the needs of workers, especially those whose duties make an unusually heavy demand on them, and to formulate scientific procedures which would help us to place men in jobs appropriate to their capacity Only a small proportion of men boarded out of the Army find suitable work too often they are left to fend for themselves, to gravitate into any job they are able to get, or to sink into a state of chronic incapacity which not only destroys their contribution to the national output but may at last bring them into the ranks of an army of misfits similar to that left by the last war Lord **BEAVERBROOK**, speaking of Watt's work on radiolocation, said "Technical developments make progress in war which sometimes outstrips all that has gone before It is the scientist who will heal our wounds It is the scientist who will protect us against the loss of our life-blood' Perhaps, but science can do nothing if the knowledge it makes available is neglected

Recently the zeal of miners has been questioned, often by people without knowledge of the risk and strain of coal-mining The accident-rate among miners is three times as great as among workers in other industries Their work is heavy and carried out in distorted postures, under working conditions which inevitably fall short of those demanded and enforced in industries above ground Men in the insured population as a whole are incapacitated by sickness for an average of 8 7 days a year, in miners the corresponding period is 18 days, and many incapacitating conditions—septic and inflammatory skin conditions, rheumatic disease, anæmia and gastritis—are two or three times as common among miners as among the general population Fatal accidents at the coal face increased from 783 in 1939 to 910 in 1940, a similar rise was observed in 1914–18. Work carrying such hazards deserves a specially good health service, and it may even be that in order to maintain his full efficiency the miner must have special concessions over and above his 8 oz of cheese when foodstuffs and clothing are being apportioned The Minister of Labour has already agreed that it would probably be better to allow the present miners 2*s* 6*d* worth of meat a week than take back another 10,000 men If further investigation shows that rationing concessions to miners are justified, no administrative difficulties should be allowed to stand in the way Colonel **WALTER ELLIOT** has suggested[1] that feeding on the spot, in works and canteens, is one way of ensuring that supplementary rations get to those who most need them It should not be an impossible piece of research to determine the quantities and types of foodstuffs needed

NEW WORK ON CARCINOGENESIS

SOME three years ago **DODDS GOLBERG, LAWSON** and **ROBINSON**[1] in an account of the œstrogenic activity of certain derivatives of diphenylethane and stilbene, drew attention to the structural resemblance between the molecules of diethylstilbœstrol (I) and œstrone (II) The comparison indicated that by ring closure there could be obtained from diethylstilbœstrol a condensed carbon ring compound similar to œstrone on the one hand and to chrysene on the other Since all the known carcinogenic hydrocarbons possess this polycyclic aromatic structure, it was decided to ascertain to what extent the condensed rings of the carcinogens might be disrupted without a complete loss of the characteristic biological activity **DODDS LAWSON** and **WILLIAMS**[2] have now reported that two tumours have developed in mice which had been painted for considerable periods with a solution in benzene of *α*-ethyl-*β*-*sec*-butylstilbene (III) This possesses a skeletal resemblance to 3 4-benzpyrene (IV) and 1 2-dimethylchrysene (V), the carcinogenic activity of which had previously been described by **COOK** and others[3] The tumours obtained by **DODDS** and his collaborators were unusual in that both were spindle-celled, one being a spindle-celled epithelioma and the second apparently a sarcoma—that is, they were of histological types not commonly encountered after the application of carcinogenic agents to the skin in mice It should also be noted that the connective-tissue tumour arose not in the painted area but subcutaneously about 2 cm away Yet there can be no doubt that these tumours were malignant and, although attempts to transplant the first failed, fragments of the sarcoma were successfully grafted in stock mice The yield of tumours is undoubtedly low, and the latent period of induction moderately long, since the first tumour developed in one of a group of seven mice after 12 months' painting, and the second in one of a group of thirteen after 15 months, these groups were the survivors from two series of twenty-five adult stock male mice with which the experiment was started It is obviously desirable that the experiment should be repeated, and this is being done If the results are confirmed, this will be the first description of carcinogenesis associated with a hydrocarbon not possessing a condensed structure

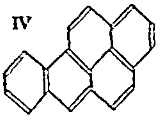
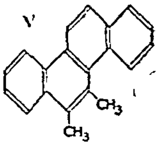
IV



V



The new observation can reasonably be expected to modify our conceptions of the relation between molecular composition and carcinogenic activity The intensive investigations of the past decade on carcinogenesis by pure chemical compounds have

---

1 See *Lancet*, Aug 16, 1941, p 203

shown this type of biological activity to depend in general on an optimal degree of molecular complexity, and in particular on certain more specific requirements While it was known that molecular simplification might proceed to a restricted extent without complete loss of potency, the carcinogenic activity of the new analogue, albeit slight, suggests that the limits of such simplification may be wider than has been supposed The systematic examination of synthetic carcinogens is directed in part to an understanding of the mechanisms by which tumour-producing compounds may be formed in vivo, as is assumed to be probable at least in certain cases Hence, evidence of the production of cancer by compounds of simpler structure than has previously been recognised is of great interest to workers engaged on this important aspect of the general problem

We have not yet been told how far α-ethyl-β-*sec*-butylstilbene acts as an œstrogen, but from its nature it seems likely to revive interest in the mutual relations of carcinogenic and œstrogenic activity This subject was originally developed through the work of Cook and Dodds, with Hewett and Lawson,[4] when they demonstrated œstrogenic activity in the carcinogenic hydrocarbons 5 6 *cyclo*penteno-1 2-benzanthracene and 3 4-benzpyrene, and proceeded to study compounds containing the same ring system as the carcinogenic hydrocarbons, but with polar groups present and some rings reduced A subsequent inclination on the part of others to exaggerate the significance of a superficial structural resemblance between œstrogenic and carcinogenic agents was followed by a phase in which the importance of any such relation tended to be minimised The latest work, and particularly the extension of it which is promised, may lead to a reinvestigation of this larger problem Yet another subject likely to be advanced is the study of the growth-inhibitory properties of carcinogenic compounds[5] in connexion both with the cellular physiology of tumour induction[6] and the search for inhibitory compounds of possible therapeutic value This property of tumour-producing hydrocarbons had already found some sort of parallel in the growth-inhibitory effects recorded by Zondek[7] for "folliculin" and by Noble[8] and Gaarenstroom and Levie[9] for diethylstilbœstrol Thus this suggestive finding, if it is fully confirmed, may stimulate inquiry in many diverse but related fields It also gives ground for the belief that although (or perhaps because) these fields have yielded richly to investigation in the past, equal or greater crops may be expected from them in future

Annotations

DRUG-FAST BACTERIA

DRUG-RESISTANCE or drug fastness was first noted in trypanosomal infections from which most of our knowledge of the phenomenon is derived It is, for example, easier to induce drug resistance in vivo than in vitro, trypanosomes rendered resistant to one drug are usually resistant to chemically-related substances, and strains may be drug fast in one host but not in another Bacteria can be trained to tolerate increasing doses of a particular antiseptic in vitro, and in practice it is often found useful to change the antiseptic in a dressing if good results are not quickly obtained Evidence suggestive of resistance to the sulphonamides among a variety of bacterial pathogens has gradually been accumulating It was early noted in the treatment of gonorrhœa with sulphanilamide that a proportion of cases failed to react to the drug, or relapsed with persistent discharge despite further treatment These refractory cases, usually attributed to insufficient early dosage, have mostly responded to treatment with the more active sulphapyridine, but even with it a small proportion of infections fail to clear up Drug resistant pneumococci also occur Thus, Ross[1] described two cultures of a pneumococcus isolated from a patient with meningitis—the first, obtained shortly after commencement of treatment with sulphapyridine, was sensitive to the drug, the second, obtained post mortem and apparently identical culturally and in virulence with the first, was drug resistant Differences in susceptibility to sulphapyridine among laboratory strains of the pneumococcus, apart from serological type, has been noted by MacLean, Rogers and Fleming[2] and a similar phenomenon has just been recorded by Florey and his colleagues for penicillin Streptococcal infections resistant to the sulphonamides are sometimes encountered, and Colebrook and Francis[3] have now isolated drug-resistant strains of hæmolytic streptococci from wounds powdered with sulphanilamide preparatory to skin-grafting These strains, detected by their growth on specially prepared sulphanilamide containing blood agar plates, belonged to four different serological types, and were apparently equally resistant to sulphapyridine, sulphathiazole and sulphadiazine Besides preventing successful skin grafts, they were responsible for secondary infection of other wounds in the same ward Such an occurrence obviously raises new problems in the control of streptococcal cross infection It is not yet known if these sulphonamide fast streptococci are also resistant to unrelated antiseptics, like proflavine or penicillin, which could replace sulphanilamide for local application Nor is it known if drug-fastness is always acquired or if some strains are naturally resistant If the acquisition of resistance is most often due, as seems likely, to inadequate early dosage with the appropriate sulphonamide, a warning is needed against the prescription, too common in general practice, of almost homœopathic doses of the drug "Strike hard and strike early" must be the watchword in chemotherapy

CONSTIPATION IN WAR-TIME

THE physical results of going short of food were fully observed in the last war, more especially among the Austrians but to some extent in our own people and notably in our British and Indian garrison at Kut This time the majority of our population have suffered, if they have suffered at all, only from monotony, but since variety in dishes and flavours aids digestion and cheers the heart the advisers of the Ministry of Food are wise to encourage the production of vegetables and herbs used in pickle-making and the conversion of most of our season's fruit crop into preserves of all kinds There have been some, however, who have found the war time diet upsetting to their bowel habits A reduction in total consumption, and especially in fruit and sometimes beer, has made some people constipated, while others have compensated for less meat with too much vegetables and have brought on diarrhœa. Apart from an unusual awareness of the abdomen, the layman can only judge the state of his intestine by the excreta, speaking of constipation when the motions are few and the fæces hard. For the doctor constipation is only present if the residue of food taken is unduly delayed. If a couple of teaspoonsful of charcoal is swallowed most of it should appear about 48 hours later, though some may be held in the large intestine and be passed a day or two afterwards. The timetable of movement through the stomach and small intestine differs little in normal people, but there is considerable variation in the rate of progress through the colon even in perfect health. Radiology has shown that there is not a steady forward movement, after an accumulation in the cæcum and proximal colon a giant contraction takes place at intervals which moves the mass of residues through the rest of the colon and is intended to result in evacuation. The mass movement seems to be set up by taking more food into the stomach, but the evacuation can usually be deferred by voluntary closure of the anal sphincter. Mass movement is thus dependent on there being enough residue in the ascending colon to form a mass, and may be reduced in force if the diet contains little indigestible material, or if the muscle of the bowel wall is weak. But in a great number of the so called constipated the delay is in the terminal colon from habitual inhibition of the defæcation reflex, and this bad habit may be encouraged by the rush and bustle of war-time and the shortage and awkwardness of lavatory accommodation to which hostels and the like are prone. The war worker, then, even if he cannot choose the diet which suits him best, will be wise to keep his meals and his times for defæcation as regular and unhurried as circumstances allow.

CONGENITAL MALARIA

THE existence of congenital malaria has been doubted because the causative parasites have never been convincingly demonstrated either in the fœtal portion of the placenta or in blood from the umbilical cord, but in view of the number of authentic case records it must now be admitted that transplacental infection does take place, and what applies to malaria applies equally to other protozoal blood infections, such as trypanosomiasis and leishmaniasis. The exact mechanism is still conjectural. Some have thought there must be a mechanical tear or other damage so that there is no longer a sharp separation between maternal and fœtal blood, but in several cases the placenta has been found apparently undamaged. It is also possible that malarial infection induces pathological changes in the placenta itself, thus facilitating the passage of parasites to the fœtal circulation, or they may reach the fœtus through a placental hæmorrhage. If a genuine case of transplacental infection is to be claimed the child must be born in a locality where malaria is not endemic and anopheline mosquitoes capable of transmitting malaria are not found, or, if the child is born in an endemic area, infection must take place at a time of the year when infected anophelines are absent. A further condition is that the interval between the birth of the child and the demonstration of parasites in the blood should be shorter than the shortest incubation period of malaria. Hoo[1] reports that on Aug. 2, 1940, an infant aged 14 days was taken to the Pædiatric Clinic in Amsterdam with the provisional diagnosis of quinine poisoning. The child was breast-fed, and the mother, who suffered from repeated attacks of malaria, had taken much quinine in the preceding days. Directly after parturition the mother had an attack of fever and 4 days afterwards malaria parasites (benign tertian) were found in her blood. The father and one of the other children (seven in the family) had also suffered from the fever which is indigenous to the Northern districts of Amsterdam. On the third day the child developed icterus neonatorum, with a loud systolic basal murmur, the spleen was not palpable. The probable diagnosis of quinine poisoning was negatived by the absence of the alkaloid in the urine, as well as in the mother's milk. At the age of 20 days ring forms of the benign tertian parasite were demonstrated in the child's blood. At no time was there high fever, an enlarged spleen or other signs of malarial infection. The provisional diagnosis of congenital heart disease was confirmed at autopsy 80 days after birth. The immediate cause of death was double otitis media. Diffuse malarial pigmentation was demonstrated in the liver and spleen. There is one loophole in the evidence—the child may have been bitten by an infected mosquito after birth—but the large number of gametocytes of *Plasmodium vivax* in the blood on the 24th day of life is definitely against an extrauterine infection. Moreover it has been shown[2] that from May 1 to Aug. 15, only 0.4% of local anophelines are infective. Hoo gives references to similar occurrences in the Dutch literature and cases have been reported from France, America and Italy. Malaria parasites have been demonstrated by Buckingham[3] in fœtal blood in China, and Jean & Van Nitsen[4] found malarial schizonts in the spleen of six stillborn children in Katanga (Belgian Congo). Examples of congenital transmission of benign tertian malaria in England have been reported. Thus Tanner and Hewlett[5] described a case in one of twins born of a malarial mother in London, and Llewelyn Jones and Brown[6] demonstrated a heavy infection in the blood of a baby aged 16 days born in Buckinghamshire, the mother having apparently acquired malaria in England during the last two months of pregnancy. Most of these records refer to benign tertian malaria, but Heiser has told of an infant aged 7 days with crescents of *P. falciparum* in its blood. Wickramasuriya[7] in Ceylon thinks that congenital transmission of the latter parasite is comparatively common there. Blacklock & Gordon[8] have effectively shown that enormous concentrations of the subtertian parasite can be demonstrated in the placentas of native women in Sierra Leone and that this parasite is responsible for premature and stillborn births. The evidence must then be accepted, and since transmission from mother to fœtus can occur it seems strange that it happens so seldom.

INTIMAL HÆMORRHAGE IN CORONARY OCCLUSION

MOST pathologists agree that coronary sclerosis is the most important common factor in the various causes of occlusion of these vessels, but many views are held as to the precise nature of the lesion leading up ot the occlusion. M. G. Nelson of Belfast[9] urges the importance of hæmorrhage in and around the intima of the coronary vessel. Authorities differ as to how the artery gets its blood-supply in health, but Nelson has confirmed that atherosclerotic vessels are well vascularised. Capillaries may be found in the intima of atherosclerotic vessels at two sites, one on the deeper aspect in close proximity to the media of the adventitia, and the other beneath the endothelium. Those at the former site are derived from the vasa vasorum of the adventitia. In both cases these vessels are of the nature of sinusoidal capillaries, they are usually found in relation to intimal atheromatous plaques and are surrounded by chronic inflammatory changes In a series of cases examined, Nelson found that hæmorrhage from these sinusoids was not uncommon Such hæmorrhages in the deeper zones of the intima healed by granulation tissue in which new capillaries were numerous An increase of fibrosis evidently then followed and predisposed the patient to a further hæmorrhage, a vicious circle then being set up The condition was present in 11 out of 17 instances investigated, and in 9 thrombotic occlusion of the lumen was also present The factors determining the intimal hæmorrhage are probably weakening of the sinusoidal wall by toxic action and transient raised intraluminar pressure induced by exertion or emotion.
